# Package: scoringutils (via r-universe)

February 6, 2025

**Title** Utilities for Scoring and Assessing Predictions **Version** 2.0.0.9000

Language en-GB

Description Facilitate the evaluation of forecasts in a convenient framework based on data.table. It allows user to to check their forecasts and diagnose issues, to visualise forecasts and missing data, to transform data before scoring, to handle missing forecasts, to aggregate scores, and to visualise the results of the evaluation. The package mostly focuses on the evaluation of probabilistic forecasts and allows evaluating several different forecast types and input formats. Find more information about the package in the Vignettes as well as in the accompanying paper, <doi:10.48550/arXiv.2205.07090>.

add\_relative\_skill

Add relative skill scores based on pairwise comparisons

# Description

Adds a columns with relative skills computed by running pairwise comparisons on the scores. For more information on the computation of relative skill, see get\_pairwise\_comparisons(). Relative skill will be calculated for the aggregation level specified in by.

# Usage

```
add_relative_skill(
   scores,
   compare = "model",
   by = NULL,
   metric = intersect(c("wis", "crps", "brier_score"), names(scores)),
   baseline = NULL
)
```

# Arguments

scores	An object of class scores (a data.table with scores and an additional attribute metrics as produced by score()).
compare	Character vector with a single colum name that defines the elements for the pairwise comparison. For example, if this is set to "model" (the default), then elements of the "model" column will be compared.
by	Character vector with column names that define further grouping levels for the pairwise comparisons. By default this is NULL and there will be one relative skill score per distinct entry of the column selected in compare. If further columns are given here, for example, by = "location" with compare = "model", then one separate relative skill score is calculated for every model in every location.
metric	A string with the name of the metric for which a relative skill shall be computed. By default this is either "crps", "wis" or "brier_score" if any of these are available.
baseline	A string with the name of a model. If a baseline is given, then a scaled relative skill with respect to the baseline will be returned. By default (NULL), relative skill will not be scaled with respect to a baseline model.

ae\_median\_quantile 5

ae\_median\_quantile

Absolute error of the median (quantile-based version)

# **Description**

Compute the absolute error of the median calculated as

observed – median prediction

The median prediction is the predicted value for which quantile\_level == 0.5. The function requires 0.5 to be among the quantile levels in quantile\_level.

# Usage

```
ae_median_quantile(observed, predicted, quantile_level)
```

# Arguments

observed Numeric vector of size n with the observed values.

predicted Numeric nxN matrix of predictive quantiles, n (number of rows) being the num-

ber of forecasts (corresponding to the number of observed values) and N (number of columns) the number of quantiles per forecast. If observed is just a single

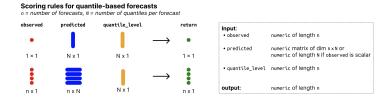

number, then predicted can just be a vector of size N.

quantile\_level Vector of of size N with the quantile levels for which predictions were made.

## Value

Numeric vector of length N with the absolute error of the median.

## **Input format**

#### See Also

ae\_median\_sample()

6 ae\_median\_sample

## **Examples**

```
observed <- rnorm(30, mean = 1:30)
predicted_values <- replicate(3, rnorm(30, mean = 1:30))
ae_median_quantile(
  observed, predicted_values, quantile_level = c(0.2, 0.5, 0.8)
)</pre>
```

ae\_median\_sample

Absolute error of the median (sample-based version)

# **Description**

Absolute error of the median calculated as

observed — median prediction

where the median prediction is calculated as the median of the predictive samples.

## Usage

```
ae_median_sample(observed, predicted)
```

## **Arguments**

observed A vector with observed values of size n

predicted nxN matrix of predictive samples, n (number of rows) being the number of data

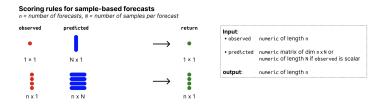

points and N (number of columns) the number of Monte Carlo samples. Alter-

natively, predicted can just be a vector of size n.

#### Value

Numeric vector of length n with the absolute errors of the median.

# **Input format**

## See Also

```
ae_median_quantile()
```

assert\_dims\_ok\_point 7

## **Examples**

```
observed <- rnorm(30, mean = 1:30)
predicted_values <- matrix(rnorm(30, mean = 1:30))
ae_median_sample(observed, predicted_values)</pre>
```

## **Description**

Function assesses whether input dimensions match. In the following, n is the number of observations / forecasts. Scalar values may be repeated to match the length of the other input. Allowed options are therefore:

- observed is vector of length 1 or length n
- predicted is:
  - a vector of of length 1 or length n
  - a matrix with n rows and 1 column

# Usage

```
assert_dims_ok_point(observed, predicted)
```

# **Arguments**

observed Input to be checked. Should be a factor of length n with exactly two levels, hold-

ing the observed values. The highest factor level is assumed to be the reference level. This means that predicted represents the probability that the observed

value is equal to the highest factor level.

predicted Input to be checked. predicted should be a vector of length n, holding proba-

bilities. Alternatively, predicted can be a matrix of size n x 1. Values represent the probability that the corresponding value in observed will be equal to the

highest available factor level.

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

```
assert_forecast.forecast_binary
```

Assert that input is a forecast object and passes validations

## **Description**

Assert that an object is a forecast object (i.e. a data.table with a class forecast and an additional class forecast\_<type> corresponding to the forecast type).

See the corresponding assert\_forecast\_<type> functions for more details on the required input formats.

# Usage

```
## S3 method for class 'forecast_binary'
assert_forecast(forecast, forecast_type = NULL, verbose = TRUE, ...)
## S3 method for class 'forecast_point'
assert_forecast(forecast, forecast_type = NULL, verbose = TRUE, ...)
## S3 method for class 'forecast_quantile'
assert_forecast(forecast, forecast_type = NULL, verbose = TRUE, ...)
## S3 method for class 'forecast_sample'
assert_forecast(forecast, forecast_type = NULL, verbose = TRUE, ...)
assert_forecast(forecast, forecast_type = NULL, verbose = TRUE, ...)
## Default S3 method:
assert_forecast(forecast, forecast_type = NULL, verbose = TRUE, ...)
```

#### **Arguments**

forecast	A forecast object (a validated data.table with predicted and observed values).
forecast_type	(optional) The forecast type you expect the forecasts to have. If the forecast type as determined by scoringutils based on the input does not match this, an error will be thrown. If NULL (the default), the forecast type will be inferred from the data.
verbose	Logical. If FALSE (default is TRUE), no messages and warnings will be created.
	Currently unused. You <i>cannot</i> pass additional arguments to scoring functions via See the <i>Customising metrics</i> section below for details on how to use purrr::partial() to pass arguments to individual metrics.

## Value

Returns NULL invisibly.

assert\_forecast\_generic 9

## **Examples**

```
forecast <- as_forecast_binary(example_binary)
assert_forecast(forecast)</pre>
```

```
assert_forecast_generic
```

Validation common to all forecast types

# **Description**

The function runs input checks that apply to all input data, regardless of forecast type. The function

- asserts that the forecast is a data.table which has columns observed and predicted
- checks the forecast type and forecast unit
- checks there are no duplicate forecasts
- if appropriate, checks the number of samples / quantiles is the same for all forecasts.

# Usage

```
assert_forecast_generic(data, verbose = TRUE)
```

# Arguments

data A data.table with forecasts and observed values that should be validated.

verbose Logical. If FALSE (default is TRUE), no messages and warnings will be created.

## Value

returns the input

# **Description**

Assert that forecast type is as expected

# Usage

```
assert_forecast_type(data, actual = get_forecast_type(data), desired = NULL)
```

## **Arguments**

data A forecast object.

actual The actual forecast type of the data desired The desired forecast type of the data

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring binary forecasts.

# Usage

assert\_input\_binary(observed, predicted)

## **Arguments**

observed Input to be checked. Should be a factor of length n with exactly two levels, hold-

ing the observed values. The highest factor level is assumed to be the reference level. This means that predicted represents the probability that the observed

value is equal to the highest factor level.

predicted Input to be checked. predicted should be a vector of length n, holding proba-

bilities. Alternatively, predicted can be a matrix of size n x 1. Values represent the probability that the corresponding value in observed will be equal to the

highest available factor level.

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

assert\_input\_categorical

Assert that inputs are correct for categorical forecasts

## **Description**

Function assesses whether the inputs correspond to the requirements for scoring categorical, i.e. either nominal or ordinal forecasts.

# Usage

assert\_input\_categorical(observed, predicted, predicted\_label, ordered = NA)

assert\_input\_interval 11

#### **Arguments**

observed Input to be checked. Should be a factor of length n with N levels holding the

observed values. n is the number of observations and N is the number of possible

outcomes the observed values can assume.

predicted Input to be checked. Should be nxN matrix of predicted probabilities, n (number

of rows) being the number of data points and N (number of columns) the number of possible outcomes the observed values can assume. If observed is just a single number, then predicted can just be a vector of size N. Values represent the probability that the corresponding value in observed will be equal to the

factor level referenced in predicted\_label.

predicted\_label

Factor of length N with N levels, where N is the number of possible outcomes

the observed values can assume.

ordered Value indicating whether factors have to be ordered or not. Defaults to NA, which

means that the check is not performed.

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

assert\_input\_interval Assert that inputs are correct for interval-based forecast

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring interval-based forecasts.

## Usage

```
assert_input_interval(observed, lower, upper, interval_range)
```

## **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

lower Input to be checked. Should be a numeric vector of size n that holds the predicted

value for the lower bounds of the prediction intervals.

upper Input to be checked. Should be a numeric vector of size n that holds the predicted

value for the upper bounds of the prediction intervals.

interval\_range Input to be checked. Should be a vector of size n that denotes the interval range

in percent. E.g. a value of 50 denotes a (25%, 75%) prediction interval.

## Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

12 assert\_input\_ordinal

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring nominal forecasts.

# Usage

```
assert_input_nominal(observed, predicted, predicted_label)
```

# Arguments

observed Input to be checked. Should be an unordered factor of length n with N lev-

els holding the observed values. n is the number of observations and N is the

number of possible outcomes the observed values can assume.

predicted Input to be checked. Should be nxN matrix of predicted probabilities, n (number

of rows) being the number of data points and N (number of columns) the number of possible outcomes the observed values can assume. If observed is just a single number, then predicted can just be a vector of size N. Values represent the probability that the corresponding value in observed will be equal to the

factor level referenced in predicted\_label.

predicted\_label

Unordered factor of length N with N levels, where N is the number of possible

outcomes the observed values can assume.

# Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

assert\_input\_ordinal Assert that inputs are correct for ordinal forecasts

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring ordinal forecasts.

#### Usage

```
assert_input_ordinal(observed, predicted, predicted_label)
```

assert\_input\_point 13

# Arguments

observed Input to be checked. Should be an ordered factor of length n with N levels hold-

ing the observed values. n is the number of observations and N is the number of

possible outcomes the observed values can assume.

predicted Input to be checked. Should be nxN matrix of predicted probabilities, n (number

of rows) being the number of data points and N (number of columns) the number of possible outcomes the observed values can assume. If observed is just a single number, then predicted can just be a vector of size N. Values represent the probability that the corresponding value in observed will be equal to factor

level referenced in predicted\_label.

predicted\_label

Ordered factor of length N with N levels, where N is the number of possible

outcomes the observed values can assume.

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

## **Description**

Function assesses whether the inputs correspond to the requirements for scoring point forecasts.

#### **Usage**

```
assert_input_point(observed, predicted)
```

# **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

predicted Input to be checked. Should be a numeric vector with the predicted values of

size n.

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

14 assert\_input\_sample

#### **Description**

Function assesses whether the inputs correspond to the requirements for scoring quantile-based forecasts.

# Usage

```
assert_input_quantile(
  observed,
  predicted,
  quantile_level,
  unique_quantile_levels = TRUE
)
```

## **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

predicted Input to be checked. Should be nxN matrix of predictive quantiles, n (number of

rows) being the number of data points and N (number of columns) the number of quantiles per forecast. If observed is just a single number, then predicted can

just be a vector of size N.

quantile\_level Input to be checked. Should be a vector of size N that denotes the quantile levels

corresponding to the columns of the prediction matrix.

unique\_quantile\_levels

Whether the quantile levels are required to be unique (TRUE, the default) or not

(FALSE).

#### Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

## Description

Function assesses whether the inputs correspond to the requirements for scoring sample-based forecasts.

## Usage

```
assert_input_sample(observed, predicted)
```

15 as\_forecast\_binary

## **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

predicted Input to be checked. Should be a numeric nxN matrix of predictive samples, n

> (number of rows) being the number of data points and N (number of columns) the number of samples per forecast. If observed is just a single number, then

predicted values can just be a vector of size N.

## Value

Returns NULL invisibly if the assertion was successful and throws an error otherwise.

as\_forecast\_binary Create a forecast object for binary forecasts

# **Description**

Process and validate a data frame (or similar) or similar with forecasts and observations. If the input passes all input checks, those functions will be converted to a forecast object. A forecast object is a data. table with a class forecast and an additional class that depends on the forecast type.

The arguments observed, predicted, etc. make it possible to rename existing columns of the input data to match the required columns for a forecast object. Using the argument forecast\_unit, you can specify the columns that uniquely identify a single forecast (and thereby removing other, unneeded columns. See section "Forecast Unit" below for details).

## Usage

```
as_forecast_binary(data, ...)
## Default S3 method:
as_forecast_binary(
  data,
  forecast_unit = NULL,
  observed = NULL,
  predicted = NULL,
)
```

#### **Arguments**

data A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.

Unused

16 as\_forecast\_binary

forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that denote the unit of a single forecast. See <a href="mailto:get\_forecast\_unit">get\_forecast\_unit</a>() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of the forecast unit (or required columns) will be removed.

observed (optional) Name of the column in data that contains the observed values. This

column will be renemed to "observed"

column will be renamed to "observed".

predicted (optional) Name of the column in data that contains the predicted values. This

column will be renamed to "predicted".

#### Value

A forecast object of class forecast\_binary

# Required input

The input needs to be a data.frame or similar with the following columns:

- observed: factor with exactly two levels representing the observed values. The highest factor level is assumed to be the reference level. This means that corresponding value in predicted represent the probability that the observed value is equal to the highest factor level.
- predicted: numeric with predicted probabilities, representing the probability that the corresponding value in observed is equal to the highest available factor level.

For convenience, we recommend an additional column model holding the name of the forecaster or model that produced a prediction, but this is not strictly necessary.

See the example\_binary data set for an example.

#### Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

The *forecast unit* or *unit* of a single forecast is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date", "forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

## See Also

```
Other functions to create forecast objects: as_forecast_nominal(), as_forecast_ordinal(), as_forecast_point(), as_forecast_quantile(), as_forecast_sample()
```

# **Examples**

```
as\_forecast\_doc\_template
```

General information on creating a forecast object

# Description

Process and validate a data.frame (or similar) or similar with forecasts and observations. If the input passes all input checks, those functions will be converted to a forecast object. A forecast object is a data.table with a class forecast and an additional class that depends on the forecast type.

The arguments observed, predicted, etc. make it possible to rename existing columns of the input data to match the required columns for a forecast object. Using the argument forecast\_unit, you can specify the columns that uniquely identify a single forecast (and thereby removing other, unneeded columns. See section "Forecast Unit" below for details).

# **Arguments**

data	A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.
forecast_unit	(optional) Name of the columns in data (after any renaming of columns) that denote the unit of a single forecast. See <pre>get_forecast_unit()</pre> for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of the forecast unit (or required columns) will be removed.
observed	(optional) Name of the column in data that contains the observed values. This column will be renamed to "observed".
predicted	(optional) Name of the column in data that contains the predicted values. This column will be renamed to "predicted".

18 as\_forecast\_generic

#### Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

The *forecast unit* or *unit* of a single forecast is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date", "forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

as\_forecast\_generic Common functionality for as\_forecast\_<type> functions

#### Description

Common functionality for as\_forecast\_<type> functions

#### **Usage**

```
as_forecast_generic(data, forecast_unit = NULL, ...)
```

## **Arguments**

data A data.frame (or similar) with predicted and observed values. See the details

section of for additional information on the required input format.

forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that

denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of

the forecast unit (or required columns) will be removed.

Named arguments that are used to rename columns. The names of the arguments

are the names of the columns that should be renamed. The values are the new

names.

#### **Details**

This function splits out part of the functionality of as\_forecast\_<type> that is the same for all as\_forecast\_<type> functions. It renames the required columns, where appropriate, and sets the forecast unit.

as\_forecast\_nominal 19

## **Description**

Process and validate a data.frame (or similar) or similar with forecasts and observations. If the input passes all input checks, those functions will be converted to a forecast object. A forecast object is a data.table with a class forecast and an additional class that depends on the forecast type.

The arguments observed, predicted, etc. make it possible to rename existing columns of the input data to match the required columns for a forecast object. Using the argument forecast\_unit, you can specify the columns that uniquely identify a single forecast (and thereby removing other, unneeded columns. See section "Forecast Unit" below for details).

## Usage

```
as_forecast_nominal(data, ...)
## Default S3 method:
as_forecast_nominal(
   data,
   forecast_unit = NULL,
   observed = NULL,
   predicted = NULL,
   predicted_label = NULL,
   ...
)
```

# **Arguments**

data A data.frame (or similar) with predicted and observed values. See the details

section of for additional information on the required input format.

... Unused

forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that

denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of

the forecast unit (or required columns) will be removed.

observed (optional) Name of the column in data that contains the observed values. This

column will be renamed to "observed".

predicted (optional) Name of the column in data that contains the predicted values. This

column will be renamed to "predicted".

predicted\_label

(optional) Name of the column in data that denotes the outcome to which a predicted probability corresponds to. This column will be renamed to "pre-

dicted\_label".

20 as\_forecast\_nominal

#### **Details**

Nominal forecasts are a form of categorical forecasts and represent a generalisation of binary forecasts to multiple outcomes. The possible outcomes that the observed values can assume are not ordered.

#### Value

A forecast object of class forecast\_nominal

## Required input

The input needs to be a data frame or similar for the default method with the following columns:

- observed: Column with observed values of type factor with N levels, where N is the number of possible outcomes. The levels of the factor represent the possible outcomes that the observed values can assume.
- predicted: numeric column with predicted probabilities. The values represent the probability that the observed value is equal to the factor level denoted in predicted\_label. Note that forecasts must be complete, i.e. there must be a probability assigned to every possible outcome and those probabilities must sum to one.
- predicted\_label: factor with N levels, denoting the outcome that the probabilities in predicted correspond to.

For convenience, we recommend an additional column model holding the name of the forecaster or model that produced a prediction, but this is not strictly necessary.

See the example\_nominal data set for an example.

## Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

The *forecast unit* or *unit of a single forecast* is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date", "forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

as\_forecast\_ordinal 21

## See Also

```
Other functions to create forecast objects: as_forecast_binary(), as_forecast_ordinal(), as_forecast_point(), as_forecast_quantile(), as_forecast_sample()
```

## **Examples**

as\_forecast\_ordinal

Create a forecast object for ordinal forecasts

# **Description**

Process and validate a data.frame (or similar) or similar with forecasts and observations. If the input passes all input checks, those functions will be converted to a forecast object. A forecast object is a data.table with a class forecast and an additional class that depends on the forecast type.

The arguments observed, predicted, etc. make it possible to rename existing columns of the input data to match the required columns for a forecast object. Using the argument forecast\_unit, you can specify the columns that uniquely identify a single forecast (and thereby removing other, unneeded columns. See section "Forecast Unit" below for details).

## Usage

```
as_forecast_ordinal(data, ...)
## Default S3 method:
as_forecast_ordinal(
   data,
   forecast_unit = NULL,
   observed = NULL,
   predicted = NULL,
   predicted_label = NULL,
   ...
)
```

#### **Arguments**

data

A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.

. . .

Unused

22 as\_forecast\_ordinal

forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that

denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of

the forecast unit (or required columns) will be removed.

observed (optional) Name of the column in data that contains the observed values. This

column will be renamed to "observed".

predicted (optional) Name of the column in data that contains the predicted values. This

column will be renamed to "predicted".

predicted\_label

(optional) Name of the column in data that denotes the outcome to which a predicted probability corresponds to. This column will be renamed to "pre-

dicted\_label".

#### **Details**

Ordinal forecasts are a form of categorical forecasts and represent a generalisation of binary forecasts to multiple outcomes. The possible outcomes that the observed values can assume are ordered.

#### Value

A forecast object of class forecast\_ordinal

# Required input

The input needs to be a data frame or similar for the default method with the following columns:

- observed: Column with observed values of type factor with N ordered levels, where N is the number of possible outcomes. The levels of the factor represent the possible outcomes that the observed values can assume.
- predicted: numeric column with predicted probabilities. The values represent the probability that the observed value is equal to the factor level denoted in predicted\_label. Note that forecasts must be complete, i.e. there must be a probability assigned to every possible outcome and those probabilities must sum to one.
- predicted\_label: factor with N levels, denoting the outcome that the probabilities in predicted correspond to.

For convenience, we recommend an additional column model holding the name of the forecaster or model that produced a prediction, but this is not strictly necessary.

See the example\_ordinal data set for an example.

#### Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

as\_forecast\_point 23

The *forecast unit* or *unit* of a single forecast is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date", "forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

```

#### **Examples**

as\_forecast\_point

Create a forecast object for point forecasts

## **Description**

When converting a forecast\_quantile object into a forecast\_point object, the 0.5 quantile is extracted and returned as the point forecast.

# Usage

```
as_forecast_point(data, ...)
## Default S3 method:
as_forecast_point(
  data,
  forecast_unit = NULL,
  observed = NULL,
  predicted = NULL,
  ...
)
```

24 as\_forecast\_point

```
## S3 method for class 'forecast_quantile'
as_forecast_point(data, ...)
```

## **Arguments**

A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.

...

Unused

forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of the forecast unit (or required columns) will be removed.

observed (optional) Name of the column in data that contains the observed values. This column will be renamed to "observed".

predicted (optional) Name of the column in data that contains the predicted values. This

column will be renamed to "predicted".

#### Value

A forecast object of class forecast\_point

## Required input

The input needs to be a data frame or similar for the default method with the following columns:

- observed: Column of type numeric with observed values.
- predicted: Column of type numeric with predicted values.

For convenience, we recommend an additional column model holding the name of the forecaster or model that produced a prediction, but this is not strictly necessary.

See the example\_point data set for an example.

25 as\_forecast\_quantile

```
as_forecast_quantile
                         Create a forecast object for quantile-based forecasts
```

# **Description**

Process and validate a data frame (or similar) or similar with forecasts and observations. If the input passes all input checks, those functions will be converted to a forecast object. A forecast object is a data. table with a class forecast and an additional class that depends on the forecast type.

The arguments observed, predicted, etc. make it possible to rename existing columns of the input data to match the required columns for a forecast object. Using the argument forecast\_unit, you can specify the columns that uniquely identify a single forecast (and thereby removing other, unneeded columns. See section "Forecast Unit" below for details).

# Usage

```
as_forecast_quantile(data, ...)
## Default S3 method:
as_forecast_quantile(
  data,
  forecast_unit = NULL,
  observed = NULL,
  predicted = NULL,
  quantile_level = NULL,
)
## S3 method for class 'forecast_sample'
as_forecast_quantile(
  data,
  probs = c(0.05, 0.25, 0.5, 0.75, 0.95),
  type = 7,
)
```

## **Arguments**

data

A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.

Unused . . .

forecast\_unit

(optional) Name of the columns in data (after any renaming of columns) that denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of the forecast unit (or required columns) will be removed.

26 as\_forecast\_quantile

observed (optional) Name of the column in data that contains the observed values. This column will be renamed to "observed". (optional) Name of the column in data that contains the predicted values. This predicted column will be renamed to "predicted". (optional) Name of the column in data that contains the quantile level of the quantile\_level predicted values. This column will be renamed to "quantile\_level". Only applicable to quantile-based forecasts. probs A numeric vector of quantile levels for which quantiles will be computed. Corresponds to the probs argument in quantile(). Type argument passed down to the quantile function. For more information, see type quantile().

#### Value

A forecast object of class forecast\_quantile

## Required input

The input needs to be a data frame or similar for the default method with the following columns:

- observed: Column of type numeric with observed values.
- predicted: Column of type numeric with predicted values. Predicted values represent quantiles of the predictive distribution.
- quantile\_level: Column of type numeric, denoting the quantile level of the corresponding predicted value. Quantile levels must be between 0 and 1.

For convenience, we recommend an additional column model holding the name of the forecaster or model that produced a prediction, but this is not strictly necessary.

See the example\_quantile data set for an example.

## Converting from forecast\_sample to forecast\_quantile

When creating a forecast\_quantile object from a forecast\_sample object, the quantiles are estimated by computing empircal quantiles from the samples via quantile(). Note that empirical quantiles are a biased estimator for the true quantiles in particular in the tails of the distribution and when the number of available samples is low.

#### Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

The *forecast unit* or *unit of a single forecast* is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date",

as\_forecast\_sample 27

"forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

#### See Also

```

## **Examples**

as\_forecast\_sample

Create a forecast object for sample-based forecasts

## Description

Process and validate a data frame (or similar) or similar with forecasts and observations. If the input passes all input checks, those functions will be converted to a forecast object. A forecast object is a data.table with a class forecast and an additional class that depends on the forecast type.

The arguments observed, predicted, etc. make it possible to rename existing columns of the input data to match the required columns for a forecast object. Using the argument forecast\_unit, you can specify the columns that uniquely identify a single forecast (and thereby removing other, unneeded columns. See section "Forecast Unit" below for details).

## Usage

```
as_forecast_sample(data, ...)
## Default S3 method:
as_forecast_sample(
   data,
   forecast_unit = NULL,
   observed = NULL,
   predicted = NULL,
   sample_id = NULL,
   ...
)
```

28 as\_forecast\_sample

#### **Arguments**

data A data frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format. Unused forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of the forecast unit (or required columns) will be removed. observed (optional) Name of the column in data that contains the observed values. This column will be renamed to "observed". predicted (optional) Name of the column in data that contains the predicted values. This column will be renamed to "predicted".

(optional) Name of the column in data that contains the sample id. This column

will be renamed to "sample\_id".

#### Value

A forecast object of class forecast\_sample

## Required input

sample\_id

The input needs to be a data.frame or similar for the default method with the following columns:

- observed: Column of type numeric with observed values.
- predicted: Column of type numeric with predicted values. Predicted values represent random samples from the predictive distribution.
- sample\_id: Column of any type with unique identifiers (unique within a single forecast) for each sample.

For convenience, we recommend an additional column model holding the name of the forecaster or model that produced a prediction, but this is not strictly necessary.

See the example\_sample\_continuous and example\_sample\_discrete data set for an example

#### Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

The *forecast unit* or *unit of a single forecast* is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date", "forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is

bias\_quantile 29

one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

#### See Also

Other functions to create forecast objects: as\_forecast\_binary(), as\_forecast\_nominal(), as\_forecast\_ordinal(), as\_forecast\_point(), as\_forecast\_quantile()

bias\_quantile

Determines bias of quantile forecasts

## **Description**

Determines bias from quantile forecasts. For an increasing number of quantiles this measure converges against the sample based bias version for integer and continuous forecasts.

## Usage

bias\_quantile(observed, predicted, quantile\_level, na.rm = TRUE)

# **Arguments**

observed Numeric vector of size n with the observed values.

predicted Numeric nxN matrix of predictive quantiles, n (number of rows) being the num-

ber of forecasts (corresponding to the number of observed values) and N (number of columns) the number of quantiles per forecast. If observed is just a single

number, then predicted can just be a vector of size N.

quantile\_level Vector of of size N with the quantile levels for which predictions were made.

Note that if this does not contain the median (0.5) then the median is imputed as

being the mean of the two innermost quantiles.

na.rm Logical. Should missing values be removed?

## **Details**

For quantile forecasts, bias is measured as

$$B_t = (1 - 2 \cdot \max\{i | q_{t,i} \in Q_t \land q_{t,i} \le x_t\}) \mathbf{1}(x_t \le q_{t,0.5}) + (1 - 2 \cdot \min\{i | q_{t,i} \in Q_t \land q_{t,i} \ge x_t\}) \mathbf{1}(x_t \ge q_{t,0.5}),$$

where  $Q_t$  is the set of quantiles that form the predictive distribution at time t and  $x_t$  is the observed value. For consistency, we define  $Q_t$  such that it always includes the element  $q_{t,0} = -\infty$  and  $q_{t,1} = \infty$ . 1() is the indicator function that is 1 if the condition is satisfied and 0 otherwise.

In clearer terms, bias  $B_t$  is:

30 bias\_sample

• 1–2· the maximum percentile rank for which the corresponding quantile is still smaller than or equal to the observed value, if the observed value is smaller than the median of the predictive distribution.

- 1-2· the minimum percentile rank for which the corresponding quantile is still larger than or equal to the observed value if the observed value is larger than the median of the predictive distribution..
- 0 if the observed value is exactly the median (both terms cancel out)

Bias can assume values between -1 and 1 and is 0 ideally (i.e. unbiased).

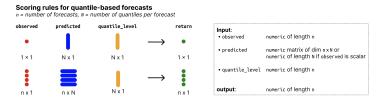

Note that if the given quantiles do not contain the median, the median is imputed as a linear interpolation of the two innermost quantiles. If the median is not available and cannot be imputed, an error will be thrown. Note that in order to compute bias, quantiles must be non-decreasing with increasing quantile levels.

For a large enough number of quantiles, the percentile rank will equal the proportion of predictive samples below the observed value, and the bias metric coincides with the one for continuous forecasts (see bias\_sample()).

#### Value

scalar with the quantile bias for a single quantile prediction

## **Input format**

# **Examples**

```
predicted <- matrix(c(1.5:23.5, 3.3:25.3), nrow = 2, byrow = TRUE) quantile_level <- c(0.01, 0.025, seq(0.05, 0.95, 0.05), 0.975, 0.99) observed <- c(15, 12.4) bias_quantile(observed, predicted, quantile_level)
```

bias\_sample

Determine bias of forecasts

## **Description**

Determines bias from predictive Monte-Carlo samples. The function automatically recognises whether forecasts are continuous or integer valued and adapts the Bias function accordingly.

bias\_sample 31

## Usage

bias\_sample(observed, predicted)

#### **Arguments**

observed A vector with observed values of size n

predicted nxN matrix of predictive samples, n (number of rows) being the number of data

points and N (number of columns) the number of Monte Carlo samples. Alter-

natively, predicted can just be a vector of size n.

#### **Details**

For continuous forecasts, Bias is measured as

$$B_t(P_t, x_t) = 1 - 2 * (P_t(x_t))$$

where  $P_t$  is the empirical cumulative distribution function of the prediction for the observed value  $x_t$ . Computationally,  $P_t(x_t)$  is just calculated as the fraction of predictive samples for  $x_t$  that are smaller than  $x_t$ .

For integer valued forecasts, Bias is measured as

$$B_t(P_t, x_t) = 1 - (P_t(x_t) + P_t(x_t + 1))$$

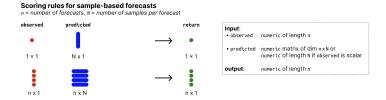

to adjust for the integer nature of the forecasts.

In both cases, Bias can assume values between -1 and 1 and is 0 ideally.

#### Value

Numeric vector of length n with the biases of the predictive samples with respect to the observed values.

# Input format

#### References

The integer valued Bias function is discussed in Assessing the performance of real-time epidemic forecasts: A case study of Ebola in the Western Area region of Sierra Leone, 2014-15 Funk S, Camacho A, Kucharski AJ, Lowe R, Eggo RM, et al. ## **Examples**

```
## integer valued forecasts
observed <- rpois(30, lambda = 1:30)
predicted <- replicate(200, rpois(n = 30, lambda = 1:30))
bias_sample(observed, predicted)

## continuous forecasts
observed <- rnorm(30, mean = 1:30)
predicted <- replicate(200, rnorm(30, mean = 1:30))
bias_sample(observed, predicted)</pre>
```

check\_columns\_present Check column names are present in a data.frame

## **Description**

The functions loops over the column names and checks whether they are present. If an issue is encountered, the function immediately stops and returns a message with the first issue encountered.

## Usage

```
check_columns_present(data, columns)
```

# Arguments

data A data.frame or similar to be checked

columns A character vector of column names to check

#### Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_dims\_ok\_point Check Inputs Have Matching Dimensions

## **Description**

Function assesses whether input dimensions match. In the following, n is the number of observations / forecasts. Scalar values may be repeated to match the length of the other input. Allowed options are therefore:

- observed is vector of length 1 or length n
- predicted is:
  - a vector of of length 1 or length n
  - a matrix with n rows and 1 column

check\_duplicates 33

## Usage

```
check_dims_ok_point(observed, predicted)
```

# **Arguments**

observed Input to be checked. Should be a factor of length n with exactly two levels, hold-

ing the observed values. The highest factor level is assumed to be the reference level. This means that predicted represents the probability that the observed

value is equal to the highest factor level.

predicted Input to be checked. predicted should be a vector of length n, holding proba-

bilities. Alternatively, predicted can be a matrix of size n x 1. Values represent the probability that the corresponding value in observed will be equal to the

highest available factor level.

## Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_duplicates

Check that there are no duplicate forecasts

# Description

Runs get\_duplicate\_forecasts() and returns a message if an issue is encountered

#### **Usage**

```
check_duplicates(data)
```

# **Arguments**

data

A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.

## Value

Returns TRUE if the check was successful and a string with an error message otherwise.

34 check\_input\_interval

check\_input\_binary

Check that inputs are correct for binary forecast

## **Description**

Function assesses whether the inputs correspond to the requirements for scoring binary forecasts.

# Usage

```
check_input_binary(observed, predicted)
```

# **Arguments**

observed Input to be checked. Should be a factor of length n with exactly two levels, hold-

ing the observed values. The highest factor level is assumed to be the reference level. This means that predicted represents the probability that the observed

value is equal to the highest factor level.

predicted Input to be checked. predicted should be a vector of length n, holding proba-

bilities. Alternatively, predicted can be a matrix of size n x 1. Values represent the probability that the corresponding value in observed will be equal to the

highest available factor level.

## Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_input\_interval

Check that inputs are correct for interval-based forecast

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring interval-based forecasts.

# Usage

```
check_input_interval(observed, lower, upper, interval_range)
```

## **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

lower Input to be checked. Should be a numeric vector of size n that holds the predicted

value for the lower bounds of the prediction intervals.

check\_input\_point 35

upper Input to be checked. Should be a numeric vector of size n that holds the predicted

value for the upper bounds of the prediction intervals.

interval\_range Input to be checked. Should be a vector of size n that denotes the interval range

in percent. E.g. a value of 50 denotes a (25%, 75%) prediction interval.

#### Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_input\_point

Check that inputs are correct for point forecast

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring point forecasts.

# Usage

```
check_input_point(observed, predicted)
```

# **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

predicted Input to be checked. Should be a numeric vector with the predicted values of

size n.

## Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_input\_quantile Check that inputs are correct for quantile-based forecast

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring quantile-based forecasts.

# Usage

```
check_input_quantile(observed, predicted, quantile_level)
```

# **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

predicted Input to be checked. Should be nxN matrix of predictive quantiles, n (number of

rows) being the number of data points and N (number of columns) the number of quantiles per forecast. If observed is just a single number, then predicted can

just be a vector of size N.

quantile\_level Input to be checked. Should be a vector of size N that denotes the quantile levels

corresponding to the columns of the prediction matrix.

#### Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_input\_sample

Check that inputs are correct for sample-based forecast

# **Description**

Function assesses whether the inputs correspond to the requirements for scoring sample-based forecasts.

## Usage

check\_input\_sample(observed, predicted)

# **Arguments**

observed Input to be checked. Should be a numeric vector with the observed values of

size n.

predicted Input to be checked. Should be a numeric nxN matrix of predictive samples, n

(number of rows) being the number of data points and N (number of columns) the number of samples per forecast. If observed is just a single number, then

predicted values can just be a vector of size N.

## Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_number\_per\_forecast

Check that all forecasts have the same number of rows

## **Description**

Helper function that checks the number of rows (corresponding e.g to quantiles or samples) per forecast. If the number of quantiles or samples is the same for all forecasts, it returns TRUE and a string with an error message otherwise.

### Usage

```
check_number_per_forecast(data, forecast_unit)
```

### **Arguments**

data A data.frame or similar to be checked

forecast\_unit Character vector denoting the unit of a single forecast.

### Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_numeric\_vector Check whether an input is an atomic vector of mode 'numeric'

### **Description**

Helper function to check whether an input is a numeric vector.

### Usage

```
check_numeric_vector(x, ...)
```

### **Arguments**

```
x input to check
```

.. Arguments passed on to checkmate::check\_numeric

lower [numeric(1)]

Lower value all elements of x must be greater than or equal to.

upper [numeric(1)]

Upper value all elements of x must be lower than or equal to.

finite [logical(1)]

Check for only finite values? Default is FALSE.

38 check\_try

```
any.missing [logical(1)]
```

Are vectors with missing values allowed? Default is TRUE.

```
all.missing [logical(1)]
```

Are vectors with no non-missing values allowed? Default is TRUE. Note that empty vectors do not have non-missing values.

```
len [integer(1)]
```

Exact expected length of x.

min.len [integer(1)]

Minimal length of x.

max.len [integer(1)]

Maximal length of x.

unique [logical(1)]

Must all values be unique? Default is FALSE.

```
sorted [logical(1)]
```

Elements must be sorted in ascending order. Missing values are ignored.

```
names [character(1)]
```

Check for names. See checkNamed for possible values. Default is "any" which performs no check at all. Note that you can use checkSubset to check for a specific set of names.

```
typed.missing [logical(1)]
```

If set to FALSE (default), all types of missing values (NA, NA\_integer\_, NA\_real\_, NA\_character\_ or NA\_character\_) as well as empty vectors are allowed while type-checking atomic input. Set to TRUE to enable strict type checking.

```
null.ok [logical(1)]
```

If set to TRUE, x may also be NULL. In this case only a type check of x is performed, all additional checks are disabled.

### Value

Returns TRUE if the check was successful and a string with an error message otherwise.

check\_try

Helper function to convert assert statements into checks

#### **Description**

Tries to execute an expression. Internally, this is used to see whether assertions fail when checking inputs (i.e. to convert an assert\_\*() statement into a check). If the expression fails, the error message is returned. If the expression succeeds, TRUE is returned.

```
check_try(expr)
```

crps\_sample 39

### Arguments

expr an expression to be evaluated

#### Value

Returns TRUE if the check was successful and a string with an error message otherwise.

crps\_sample

(Continuous) ranked probability score

# Description

Wrapper around the crps\_sample() function from the scoringRules package. Can be used for continuous as well as integer valued forecasts

The Continuous ranked probability score (CRPS) can be interpreted as the sum of three components: overprediction, underprediction and dispersion. "Dispersion" is defined as the CRPS of the median forecast \$m\$. If an observation \$y\$ is greater than \$m\$ then overprediction is defined as the CRPS of the forecast for \$y\$ minus the dispersion component, and underprediction is zero. If, on the other hand, \$y<m\$ then underprediction is defined as the CRPS of the forecast for \$y\$ minus the dispersion component, and overprediction is zero.

The overprediction, underprediction and dispersion components correspond to those of the wis().

## Usage

```
crps_sample(observed, predicted, separate_results = FALSE, ...)
dispersion_sample(observed, predicted, ...)
overprediction_sample(observed, predicted, ...)
underprediction_sample(observed, predicted, ...)
```

# **Arguments**

observed A vector with observed values of size n

predicted nxN matrix of predictive samples, n (number of rows) being the number of data

points and N (number of columns) the number of Monte Carlo samples. Alter-

natively, predicted can just be a vector of size n.

separate\_results

Logical. If TRUE (default is FALSE), then the separate parts of the CRPS (dispersion penalty, penalties for over- and under-prediction) get returned as separate elements of a list. If you want a data.frame instead, simply call as.data.frame()

on the output.

Additional arguments passed on to crps\_sample() from functions overprediction\_sample(),

underprediction\_sample() and dispersion\_sample().

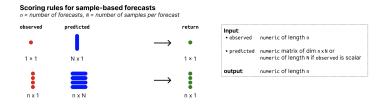

40 dss\_sample

### Value

Vector with scores.

dispersion\_sample(): a numeric vector with dispersion values (one per observation). overprediction\_quantile(): a numeric vector with overprediction values (one per observation). underprediction\_quantile(): a numeric vector with underprediction values (one per observation).

## **Input format**

#### References

Alexander Jordan, Fabian Krüger, Sebastian Lerch, Evaluating Probabilistic Forecasts with scoringRules, https://www.jstatsoft.org/article/view/v090i12

## **Examples**

```
observed <- rpois(30, lambda = 1:30)
predicted <- replicate(200, rpois(n = 30, lambda = 1:30))
crps_sample(observed, predicted)</pre>
```

dss\_sample

Dawid-Sebastiani score

## **Description**

Wrapper around the dss\_sample() function from the **scoringRules** package.

### Usage

```
dss_sample(observed, predicted, ...)
```

### **Arguments**

observed A vector with observed values of size n

nxN matrix of predictive samples, n (number of rows) being the number of data
points and N (number of columns) the number of Monte Carlo samples. Alternatively, predicted can just be a vector of size n.

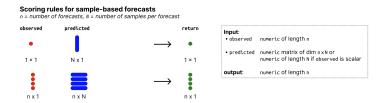

Additional arguments passed to dss\_sample() from the scoringRules package.

example\_binary 41

### Value

Vector with scores.

### **Input format**

#### References

Alexander Jordan, Fabian Krüger, Sebastian Lerch, Evaluating Probabilistic Forecasts with scoringRules, https://www.jstatsoft.org/article/view/v090i12

### **Examples**

```
observed <- rpois(30, lambda = 1:30)
predicted <- replicate(200, rpois(n = 30, lambda = 1:30))
dss_sample(observed, predicted)</pre>
```

example\_binary

Binary forecast example data

## Description

A data set with binary predictions for COVID-19 cases and deaths constructed from data submitted to the European Forecast Hub.

### Usage

```
example_binary
```

## Format

An object of class forecast\_binary (see as\_forecast\_binary()) with the following columns:

location the country for which a prediction was made

location\_name name of the country for which a prediction was made

target\_end\_date the date for which a prediction was made

target\_type the target to be predicted (cases or deaths)

**observed** A factor with observed values

forecast\_date the date on which a prediction was made

42 example\_nominal

model name of the model that generated the forecastshorizon forecast horizon in weekspredicted predicted value

#### **Details**

Predictions in the data set were constructed based on the continuous example data by looking at the number of samples below the mean prediction. The outcome was constructed as whether or not the actually observed value was below or above that mean prediction. This should not be understood as sound statistical practice, but rather as a practical way to create an example data set.

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

#### Source

https://github.com/european-modelling-hubs/covid19-forecast-hub-europe\_archive/commit/a42867b1ea152c57e25b04f9faa26cfd4bfd8fa6/

example\_nominal

Nominal example data

### **Description**

A data set with predictions for COVID-19 cases and deaths submitted to the European Forecast Hub.

### Usage

example\_nominal

### **Format**

An object of class forecast\_nominal (see as\_forecast\_nominal()) with the following columns:

location the country for which a prediction was made

target\_end\_date the date for which a prediction was made

target\_type the target to be predicted (cases or deaths)

observed Numeric: observed values

location\_name name of the country for which a prediction was made

forecast\_date the date on which a prediction was made

predicted\_label outcome that a probabilty corresponds to

predicted predicted value

model name of the model that generated the forecasts

horizon forecast horizon in weeks

example\_ordinal 43

### **Details**

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

#### Source

example\_ordinal

Ordinal example data

## **Description**

A data set with predictions for COVID-19 cases and deaths submitted to the European Forecast Hub.

# Usage

example\_ordinal

## **Format**

An object of class forecast\_ordinal (see as\_forecast\_ordinal()) with the following columns:

location the country for which a prediction was made

target\_end\_date the date for which a prediction was made

target\_type the target to be predicted (cases or deaths)

observed Numeric: observed values

location\_name name of the country for which a prediction was made

forecast\_date the date on which a prediction was made

predicted\_label outcome that a probabilty corresponds to

predicted predicted value

model name of the model that generated the forecasts

horizon forecast horizon in weeks

### **Details**

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

### Source

44 example\_point

example\_point

Point forecast example data

## **Description**

A data set with predictions for COVID-19 cases and deaths submitted to the European Forecast Hub. This data set is like the quantile example data, only that the median has been replaced by a point forecast.

### Usage

example\_point

### **Format**

An object of class forecast\_point (see as\_forecast\_point()) with the following columns:

location the country for which a prediction was made

target\_end\_date the date for which a prediction was made

**target\_type** the target to be predicted (cases or deaths)

observed observed values

location\_name name of the country for which a prediction was made

forecast\_date the date on which a prediction was made

predicted predicted value

model name of the model that generated the forecasts

horizon forecast horizon in weeks

#### **Details**

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

example\_quantile 45

example\_quantile

Quantile example data

# Description

A data set with predictions for COVID-19 cases and deaths submitted to the European Forecast Hub.

## Usage

```
example_quantile
```

#### **Format**

An object of class forecast\_quantile (see as\_forecast\_quantile()) with the following columns:

location the country for which a prediction was made

target\_end\_date the date for which a prediction was made

**target\_type** the target to be predicted (cases or deaths)

observed Numeric: observed values

**location\_name** name of the country for which a prediction was made

forecast\_date the date on which a prediction was made

quantile\_level quantile level of the corresponding prediction

predicted predicted value

model name of the model that generated the forecasts

horizon forecast horizon in weeks

#### **Details**

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

### **Source**

example\_sample\_continuous

Continuous forecast example data

## **Description**

A data set with continuous predictions for COVID-19 cases and deaths constructed from data submitted to the European Forecast Hub.

### Usage

example\_sample\_continuous

### **Format**

An object of class forecast\_sample (see as\_forecast\_sample()) with the following columns:

**location** the country for which a prediction was made

target\_end\_date the date for which a prediction was made

target\_type the target to be predicted (cases or deaths)

observed observed values

location\_name name of the country for which a prediction was made

**forecast\_date** the date on which a prediction was made

model name of the model that generated the forecasts

horizon forecast horizon in weeks

predicted predicted value

**sample\_id** id for the corresponding sample

#### **Details**

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

## Source

example\_sample\_discrete

Discrete forecast example data

## **Description**

A data set with integer predictions for COVID-19 cases and deaths constructed from data submitted to the European Forecast Hub.

### Usage

```
example_sample_discrete
```

### **Format**

An object of class forecast\_sample (see as\_forecast\_sample()) with the following columns:

location the country for which a prediction was made

target\_end\_date the date for which a prediction was made

target\_type the target to be predicted (cases or deaths)

observed observed values

location\_name name of the country for which a prediction was made

forecast\_date the date on which a prediction was made

model name of the model that generated the forecasts

horizon forecast horizon in weeks

predicted predicted value

**sample\_id** id for the corresponding sample

#### **Details**

The data was created using the script create-example-data.R in the inst/ folder (or the top level folder in a compiled package).

## Source

48 get\_coverage

Calculate correlation between metrics
---------------------------------------

## **Description**

Calculate the correlation between different metrics for a data.frame of scores as produced by score().

### Usage

```
get_correlations(scores, metrics = get_metrics.scores(scores), ...)
```

## **Arguments**

scores	An object of class scores (a data.table with scores and an additional attribute metrics as produced by score()).
metrics	A character vector with the metrics to show. If set to NULL (default), all metrics present in scores will be shown.
	Additional arguments to pass down to cor().

## Value

An object of class scores (a data.table with an additional attribute metrics holding the names of the scores) with correlations between different metrics

### **Examples**

```
library(magrittr) # pipe operator
scores <- example_quantile %>%
  as_forecast_quantile() %>%
  score()
get_correlations(scores)
```

get\_coverage

Get quantile and interval coverage values for quantile-based forecasts

## **Description**

For a validated forecast object in a quantile-based format (see as\_forecast\_quantile() for more information), this function computes:

- interval coverage of central prediction intervals
- quantile coverage for predictive quantiles
- the deviation between desired and actual coverage (both for interval and quantile coverage)

get\_coverage 49

Coverage values are computed for a specific level of grouping, as specified in the by argument. By default, coverage values are computed per model.

#### Interval coverage

Interval coverage for a given interval range is defined as the proportion of observations that fall within the corresponding central prediction intervals. Central prediction intervals are symmetric around the median and formed by two quantiles that denote the lower and upper bound. For example, the 50% central prediction interval is the interval between the 0.25 and 0.75 quantiles of the predictive distribution.

### Quantile coverage

Quantile coverage for a given quantile level is defined as the proportion of observed values that are smaller than the corresponding predictive quantile. For example, the 0.5 quantile coverage is the proportion of observed values that are smaller than the 0.5 quantile of the predictive distribution. Just as above, for a single observation and the quantile of a single predictive distribution, the value will either be TRUE or FALSE.

#### Coverage deviation

The coverage deviation is the difference between the desired coverage (can be either interval or quantile coverage) and the actual coverage. For example, if the desired coverage is 90% and the actual coverage is 80%, the coverage deviation is -0.1.

### Usage

```
get_coverage(forecast, by = "model")
```

# **Arguments**

forecast A forecast object (a validated data.table with predicted and observed values).

by character vector that denotes the level of grouping for which the coverage values

should be computed. By default ("model"), one coverage value per model will

be returned.

### Value

A data.table with columns as specified in by and additional columns for the coverage values described above

a data.table with columns "interval\_coverage", "interval\_coverage\_deviation", "quantile\_coverage", "quantile\_coverage\_deviation" and the columns specified in by.

#### **Examples**

```
library(magrittr) # pipe operator
example_quantile %>%
   as_forecast_quantile() %>%
   get_coverage(by = "model")
```

50 get\_forecast\_counts

```
get_duplicate_forecasts
```

Find duplicate forecasts

### **Description**

Internal helper function to identify duplicate forecasts, i.e. instances where there is more than one forecast for the same prediction target.

## Usage

```
get_duplicate_forecasts(data, forecast_unit = NULL, counts = FALSE)
```

### **Arguments**

data A data.frame (or similar) with predicted and observed values. See the details

section of for additional information on the required input format.

forecast\_unit (optional) Name of the columns in data (after any renaming of columns) that

denote the unit of a single forecast. See get\_forecast\_unit() for details. If NULL (the default), all columns that are not required columns are assumed to form the unit of a single forecast. If specified, all columns that are not part of

the forecast unit (or required columns) will be removed.

counts Should the output show the number of duplicates per forecast unit instead of the

individual duplicated rows? Default is FALSE.

#### Value

A data.frame with all rows for which a duplicate forecast was found

# Examples

```
example <- rbind(example_quantile, example_quantile[1000:1010])
get_duplicate_forecasts(example)</pre>
```

get\_forecast\_counts

Count number of available forecasts

## **Description**

Given a data set with forecasts, this function counts the number of available forecasts. The level of grouping can be specified using the by argument (e.g. to count the number of forecasts per model, or the number of forecasts per model and location). This is useful to determine whether there are any missing forecasts.

get\_forecast\_type 51

### Usage

```
get_forecast_counts(
  forecast,
  by = get_forecast_unit(forecast),
  collapse = c("quantile_level", "sample_id")
)
```

#### **Arguments**

forecast A forecast object (a validated data.table with predicted and observed values).

by character vector or NULL (the default) that denotes the categories over which the

number of forecasts should be counted. By default this will be the unit of a single forecast (i.e. all available columns (apart from a few "protected" columns such as 'predicted' and 'observed') plus "quantile\_level" or "sample\_id" where

present).

collapse character vector (default: c("quantile\_level", "sample\_id") with names

of categories for which the number of rows should be collapsed to one when counting. For example, a single forecast is usually represented by a set of several quantiles or samples and collapsing these to one makes sure that a single forecast only gets counted once. Setting collapse = c() would mean that all quantiles /

samples would be counted as individual forecasts.

# Value

A data.table with columns as specified in by and an additional column "count" with the number of forecasts.

### **Examples**

```
library(magrittr) # pipe operator
example_quantile %>%
   as_forecast_quantile() %>%
   get_forecast_counts(by = c("model", "target_type"))
```

get\_forecast\_type

Get forecast type from forecast object

### **Description**

Get forecast type from forecast object

```
get_forecast_type(forecast)
```

52 get\_forecast\_unit

#### **Arguments**

forecast

A forecast object (a validated data.table with predicted and observed values).

#### Value

Character vector of length one with the forecast type.

get\_forecast\_unit

Get unit of a single forecast

#### **Description**

Helper function to get the unit of a single forecast, i.e. the column names that define where a single forecast was made for. This just takes all columns that are available in the data and subtracts the columns that are protected, i.e. those returned by get\_protected\_columns() as well as the names of the metrics that were specified during scoring, if any.

### Usage

```
get_forecast_unit(data)
```

#### **Arguments**

data

A data.frame (or similar) with predicted and observed values. See the details section of for additional information on the required input format.

#### Value

A character vector with the column names that define the unit of a single forecast

#### Forecast unit

In order to score forecasts, scoringutils needs to know which of the rows of the data belong together and jointly form a single forecasts. This is easy e.g. for point forecast, where there is one row per forecast. For quantile or sample-based forecasts, however, there are multiple rows that belong to a single forecast.

The *forecast unit* or *unit* of a single forecast is then described by the combination of columns that uniquely identify a single forecast. For example, we could have forecasts made by different models in various locations at different time points, each for several weeks into the future. The forecast unit could then be described as forecast\_unit = c("model", "location", "forecast\_date", "forecast\_horizon"). scoringutils automatically tries to determine the unit of a single forecast. It uses all existing columns for this, which means that no columns must be present that are unrelated to the forecast unit. As a very simplistic example, if you had an additional row, "even", that is one if the row number is even and zero otherwise, then this would mess up scoring as scoringutils then thinks that this column was relevant in defining the forecast unit.

In order to avoid issues, we recommend setting the forecast unit explicitly, using the forecast\_unit argument. This will simply drop unneeded columns, while making sure that all necessary, 'protected columns' like "predicted" or "observed" are retained.

get\_metrics 53

get\_metrics

Get metrics

## **Description**

Generic function to to obtain default metrics available for scoring or metrics that were used for scoring.

- If called on a forecast object it returns a list of functions that can be used for scoring.
- If called on a scores object (see score()), it returns a character vector with the names of the metrics that were used for scoring.

See the documentation for the actual methods in the See Also section below for more details. Alternatively call ?get\_metrics.<forecast\_type> or ?get\_metrics.scores.

#### Usage

```
get_metrics(x, ...)
```

## Arguments

- x A forecast or scores object.
- ... Additional arguments passed to the method.

### See Also

```
Other get_metrics functions: get_metrics.forecast_binary(), get_metrics.forecast_nominal(), get_metrics.forecast_ordinal(), get_metrics.forecast_point(), get_metrics.forecast_quantile(), get_metrics.forecast_sample(), get_metrics.scores()
```

```
get_metrics.forecast_binary
```

Get default metrics for binary forecasts

# Description

For binary forecasts, the default scoring rules are:

```
• "brier_score" = brier_score()
```

```
• "log_score" = logs_binary()
```

```
## S3 method for class 'forecast_binary'
get_metrics(x, select = NULL, exclude = NULL, ...)
```

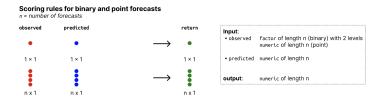

### **Arguments**

x	A forecast object (a validated data.table with predicted and observed values, see as_forecast_binary()).
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.
	unused

### Value

A list of scoring functions.

## **Input format**

## See Also

```
Other get_metrics functions: get_metrics(), get_metrics.forecast_nominal(), get_metrics.forecast_ordinal(), get_metrics.forecast_point(), get_metrics.forecast_quantile(), get_metrics.forecast_sample(), get_metrics.scores()
```

## **Examples**

# **Description**

For nominal forecasts, the default scoring rule is:

```
• "log_score" = logs_categorical()
```

### Usage

```
## S3 method for class 'forecast_nominal'
get_metrics(x, select = NULL, exclude = NULL, ...)
```

### **Arguments**

x	A forecast object (a validated data.table with predicted and observed values, see as_forecast_binary()).
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.
	unused

#### See Also

```
Other get_metrics functions: get_metrics(), get_metrics.forecast_binary(), get_metrics.forecast_ordinal(), get_metrics.forecast_point(), get_metrics.forecast_quantile(), get_metrics.forecast_sample(), get_metrics.scores()
```

## **Examples**

```
get_metrics(example_nominal)
```

```
get_metrics.forecast_ordinal

Get default metrics for nominal forecasts
```

## **Description**

For ordinal forecasts, the default scoring rules are:

```
"log_score" = logs_categorical()"rps" = rps_ordinal()
```

```
## S3 method for class 'forecast_ordinal'
get_metrics(x, select = NULL, exclude = NULL, ...)
```

### **Arguments**

X	A forecast object (a validated data.table with predicted and observed values, see as_forecast_binary()).
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.
	unused

### See Also

```
Other get_metrics functions: get_metrics(), get_metrics.forecast_binary(), get_metrics.forecast_nominal(), get_metrics.forecast_point(), get_metrics.forecast_quantile(), get_metrics.forecast_sample(), get_metrics.scores()
```

# **Examples**

```
get_metrics(example_ordinal)

get_metrics.forecast_point

Get default metrics for point forecasts
```

### **Description**

For point forecasts, the default scoring rules are:

```
 "ae_point" = ae() "se_point" = se() "ape" = ape()
```

A note of caution: Every scoring rule for a point forecast is implicitly minimised by a specific aspect of the predictive distribution (see Gneiting, 2011).

The mean squared error, for example, is only a meaningful scoring rule if the forecaster actually reported the mean of their predictive distribution as a point forecast. If the forecaster reported the median, then the mean absolute error would be the appropriate scoring rule. If the scoring rule and the predictive task do not align, the results will be misleading.

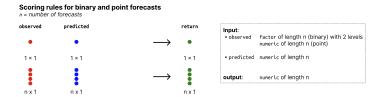

Failure to respect this correspondence can lead to grossly misleading results! Consider the example in the section below.

```
## S3 method for class 'forecast_point'
get_metrics(x, select = NULL, exclude = NULL, ...)
```

# Arguments

x	A forecast object (a validated data.table with predicted and observed values, see as_forecast_binary()).
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.
	unused

## **Input format**

### References

#### See Also

```
Other get_metrics functions: get_metrics(), get_metrics.forecast_binary(), get_metrics.forecast_nominal(), get_metrics.forecast_ordinal(), get_metrics.forecast_quantile(), get_metrics.forecast_sample(), get_metrics.scores()
```

# **Examples**

```
get_metrics(example_point, select = "ape")
library(magrittr)
set.seed(123)
n <- 500
observed <- rnorm(n, 5, 4)^2

predicted_mu <- mean(observed)
predicted_not_mu <- predicted_mu - rnorm(n, 10, 2)

df <- data.frame(
   model = rep(c("perfect", "bad"), each = n),
   predicted = c(rep(predicted_mu, n), predicted_not_mu),
   observed = rep(observed, 2),
   id = rep(1:n, 2)
) %>%
   as_forecast_point()
```

```
score(df) %>%
summarise_scores()
```

```
get_metrics.forecast_quantile
```

Get default metrics for quantile-based forecasts

### **Description**

For quantile-based forecasts, the default scoring rules are:

```
• "wis" = wis()
```

- "overprediction" = overprediction\_quantile()
- "underprediction" = underprediction\_quantile()
- "dispersion" = dispersion\_quantile()
- "bias" = bias\_quantile()
- "interval\_coverage\_50" = interval\_coverage()
- "interval\_coverage\_90" = purrr::partial( interval\_coverage, interval\_range = 90 )
- "ae\_median" = ae\_median\_quantile()

Note: The interval\_coverage\_90 scoring rule is created by modifying interval\_coverage(), making use of the function purrr::partial(). This construct allows the function to deal with arbitrary arguments in ..., while making sure that only those that interval\_coverage() can accept get passed on to it. interval\_range = 90 is set in the function definition, as passing an argument interval\_range = 90 to score() would mean it would also get passed to interval\_coverage\_50.

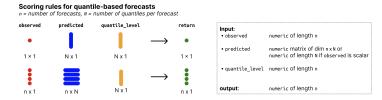

# Usage

```
## S3 method for class 'forecast_quantile'
get_metrics(x, select = NULL, exclude = NULL, ...)
```

### **Arguments**

X	A forecast object (a validated data.table with predicted and observed values, see as_forecast_binary()).
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.
	unused

get_metrics(x, select = NULL, exclude = NULL, ...)
```

60 get\_metrics.scores

### Arguments

x	A forecast object (a validated data.table with predicted and observed values, see as_forecast_binary()).
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.
	unused

### **Input format**

#### See Also

```
Other get_metrics functions: get_metrics(), get_metrics.forecast_binary(), get_metrics.forecast_nominal(), get_metrics.forecast_ordinal(), get_metrics.forecast_point(), get_metrics.forecast_quantile(), get_metrics.scores()
```

## **Examples**

### Description

When applying a scoring rule via score(), the names of the scoring rules become column names of the resulting data.table. In addition, an attribute metrics will be added to the output, holding the names of the scores as a vector.

This is done so that functions like get\_forecast\_unit() or summarise\_scores() can still identify which columns are part of the forecast unit and which hold a score.

get\_metrics() accesses and returns the metrics attribute. If there is no attribute, the function will return NULL (or, if error = TRUE will produce an error instead). In addition, it checks the column names of the input for consistency with the data stored in the metrics attribute.

### Handling a missing or inconsistent metrics attribute:

If the metrics attribute is missing or is not consistent with the column names of the data.table, you can either

- run score() again, specifying names for the scoring rules manually, or
- add/update the attribute manually using attr(scores, "metrics") <- c("names", "of", "your", "scores") (the order does not matter).

#### Usage

```
## S3 method for class 'scores'
get_metrics(x, error = FALSE, ...)
```

### **Arguments**

```
x A scores object, (a data.table with an attribute metrics as produced by score()).

error Throw an error if there is no attribute called metrics? Default is FALSE.

... unused
```

#### Value

Character vector with the names of the scoring rules that were used for scoring.

#### See Also

```
Other get_metrics functions: get_metrics(), get_metrics.forecast_binary(), get_metrics.forecast_nominal(), get_metrics.forecast_ordinal(), get_metrics.forecast_point(), get_metrics.forecast_quantile(), get_metrics.forecast_sample()
```

```
get_pairwise_comparisons
```

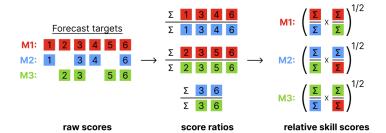

Obtain pairwise comparisons between models

### **Description**

Compare scores obtained by different models in a pairwise tournament. All combinations of two models are compared against each other based on the overlapping set of available forecasts common to both models.

The input should be a scores object as produced by score(). Note that adding additional unrelated columns can unpredictably change results, as all present columns are taken into account when determining the set of overlapping forecasts between two models.

The output of the pairwise comparisons is a set of mean score ratios, relative skill scores and p-values.

#### Mean score ratios

For every pair of two models, a mean score ratio is computed. This is simply the mean score of the first model divided by the mean score of the second. Mean score ratios are computed based on the set of overlapping forecasts between the two models. That means that only scores for those targets are taken into account for which both models have submitted a forecast.

#### (Scaled) Relative skill scores

The relative score of a model is the geometric mean of all mean score ratios which involve that model. If a baseline is provided, scaled relative skill scores will be calculated as well. Scaled relative skill scores are simply the relative skill score of a model divided by the relative skill score of the baseline model.

#### p-values

In addition, the function computes p-values for the comparison between two models (again based on the set of overlapping forecasts). P-values can be computed in two ways: based on a nonparametric Wilcoxon signed-rank test (internally using wilcox.test() with paired = TRUE) or based on a permutation test. The permutation test is based on the difference in mean scores between two models. The default null hypothesis is that the mean score difference is zero (see permutation\_test()). Adjusted p-values are computed by calling p.adjust() on the raw p-values.

The code for the pairwise comparisons is inspired by an implementation by Johannes Bracher. The implementation of the permutation test follows the function permutationTest from the surveillance package by Michael Höhle, Andrea Riebler and Michaela Paul.

### Usage

```
get_pairwise_comparisons(
   scores,
   compare = "model",
   by = NULL,
   metric = intersect(c("wis", "crps", "brier_score"), names(scores)),
   baseline = NULL,
   ...
)
```

#### **Arguments**

scores

An object of class scores (a data.table with scores and an additional attribute metrics as produced by score()).

compare	Character vector with a single colum name that defines the elements for the pairwise comparison. For example, if this is set to "model" (the default), then elements of the "model" column will be compared.
by	Character vector with column names that define further grouping levels for the pairwise comparisons. By default this is NULL and there will be one relative skill score per distinct entry of the column selected in compare. If further columns are given here, for example, by = "location" with compare = "model", then one separate relative skill score is calculated for every model in every location.
metric	A string with the name of the metric for which a relative skill shall be computed. By default this is either "crps", "wis" or "brier_score" if any of these are available.
baseline	A string with the name of a model. If a baseline is given, then a scaled relative skill with respect to the baseline will be returned. By default (NULL), relative skill will not be scaled with respect to a baseline model.
	Additional arguments for the comparison between two models. See compare_forecasts() for more information.

## Value

A data.table with the results of pairwise comparisons containing the mean score ratios (mean\_scores\_ratio), unadjusted (pval) and adjusted (adj\_pval) p-values, and relative skill values of each model (...\_relative\_skill). If a baseline model is given then the scaled relative skill is reported as well (...\_scaled\_relative\_skill).

```

## **Examples**

```
library(magrittr) # pipe operator

scores <- example_quantile %>%
    as_forecast_quantile() %>%
    score()

pairwise <- get_pairwise_comparisons(scores, by = "target_type")
pairwise2 <- get_pairwise_comparisons(
    scores, by = "target_type", baseline = "EuroCOVIDhub-baseline"
)

library(ggplot2)
plot_pairwise_comparisons(pairwise, type = "mean_scores_ratio") +
    facet_wrap(~target_type)</pre>
```

## **Description**

Generate a Probability Integral Transformation (PIT) histogram for validated forecast objects. See the examples for how to plot the result of this function.

#### Usage

```
## S3 method for class 'forecast_quantile'
get_pit_histogram(forecast, num_bins = NULL, breaks = NULL, by, ...)

## S3 method for class 'forecast_sample'
get_pit_histogram(
  forecast,
    num_bins = 10,
    breaks = NULL,
    by,
    integers = c("nonrandom", "random", "ignore"),
    n_replicates = NULL,
    ...
)

get_pit_histogram(forecast, num_bins, breaks, by, ...)

## Default S3 method:
get_pit_histogram(forecast, num_bins, breaks, by, ...)
```

# Arguments

forecast

A forecast object (a validated data.table with predicted and observed values).

num\_bins

The number of bins in the PIT histogram. For sample-based forecasts, the default is 10 bins. For quantile-based forecasts, the default is one bin for each available quantile. You can control the number of bins by supplying a number. This is fine for sample-based pit histograms, but may fail for quantile-based formats. In this case it is preferred to supply explicit breaks points using the breaks argument.

breaks

Numeric vector with the break points for the bins in the PIT histogram. This is preferred when creating a PIT histogram based on quantile-based data. Default is NULL and breaks will be determined by num\_bins. If breaks is used, num\_bins will be ignored. 0 and 1 will always be added as left and right bounds, respectively.

by	Character vector with the columns according to which the PIT values shall be grouped. If you e.g. have the columns 'model' and 'location' in the input data and want to have a PIT histogram for every model and location, specify by = c("model", "location").
	Currently unused. You <i>cannot</i> pass additional arguments to scoring functions via See the <i>Customising metrics</i> section below for details on how to use purrr::partial() to pass arguments to individual metrics.
integers	How to handle integer forecasts (count data). This is based on methods described Czado et al. (2007). If "nonrandom" (default) the function will use the non-randomised PIT method. If "random", will use the randomised PIT method. If "ignore", will treat integer forecasts as if they were continuous.
n_replicates	The number of draws for the randomised PIT for discrete predictions. Will be ignored if forecasts are continuous or integers is not set to random.

#### Value

A data.table with density values for each bin in the PIT histogram.

```

interval\_coverage

get_type	Get type of a vector or matrix of observed values or predictions	

## Description

Internal helper function to get the type of a vector (usually of observed or predicted values). The function checks whether the input is a factor, or else whether it is integer (or can be coerced to integer) or whether it's continuous.

### Usage

```
get_type(x)
```

### **Arguments**

Х

Input the type should be determined for.

#### Value

Character vector of length one with either "classification", "integer", or "continuous".

interval_coverage	Interval coverage (for quantile-based forecasts)	
-------------------	--	--

## **Description**

Check whether the observed value is within a given central prediction interval. The prediction interval is defined by a lower and an upper bound formed by a pair of predictive quantiles. For example, a 50% prediction interval is formed by the 0.25 and 0.75 quantiles of the predictive distribution.

# Usage

```
interval_coverage(observed, predicted, quantile_level, interval_range = 50)
```

# **Arguments**

observed	Numeric vector of size n with the observed values.
predicted	Numeric nxN matrix of predictive quantiles, n (number of rows) being the number of forecasts (corresponding to the number of observed values) and N (number of columns) the number of quantiles per forecast. If observed is just a single number, then predicted can just be a vector of size $N$ .
quantile_level	Vector of of size N with the quantile levels for which predictions were made.
interval_range	A single number with the range of the prediction interval in percent (e.g. 50 for

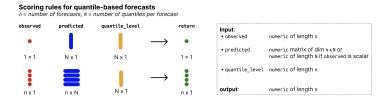

a 50% prediction interval) for which you want to compute interval coverage.

interval\_score 67

### Value

A vector of length n with elements either TRUE, if the observed value is within the corresponding prediction interval, and FALSE otherwise.

### **Input format**

## **Examples**

```
observed <- c(1, -15, 22)
predicted <- rbind(
    c(-1, 0, 1, 2, 3),
    c(-2, 1, 2, 2, 4),
        c(-2, 0, 3, 3, 4)
)
quantile_level <- c(0.1, 0.25, 0.5, 0.75, 0.9)
interval_coverage(observed, predicted, quantile_level)</pre>
```

interval\_score

Interval score

## **Description**

Proper Scoring Rule to score quantile predictions, following Gneiting and Raftery (2007). Smaller values are better.

The score is computed as

$$score = (upper-lower) + \frac{2}{\alpha}(lower-observed) * \mathbf{1}(observed < lower) + \frac{2}{\alpha}(observed-upper) * \mathbf{1}(observed > upper)$$

where  $\mathbf{1}()$  is the indicator function and indicates how much is outside the prediction interval.  $\alpha$  is the decimal value that indicates how much is outside the prediction interval.

To improve usability, the user is asked to provide an interval range in percentage terms, i.e. interval\_range = 90 (percent) for a 90 percent prediction interval. Correspondingly, the user would have to provide the 5% and 95% quantiles (the corresponding alpha would then be 0.1). No specific distribution is assumed, but the interval has to be symmetric around the median (i.e you can't use the 0.1 quantile as the lower bound and the 0.7 quantile as the upper bound). Non-symmetric quantiles can be scored using the function quantile\_score().

68 interval\_score

### Usage

```
interval_score(
  observed,
  lower,
  upper,
  interval_range,
  weigh = TRUE,
  separate_results = FALSE
)
```

### **Arguments**

observed A vector with observed values of size n

lower Vector of size n with the prediction for the lower quantile of the given interval

range.

upper Vector of size n with the prediction for the upper quantile of the given interval

range.

interval\_range Numeric vector (either a single number or a vector of size n) with the range of

the prediction intervals. For example, if you're forecasting the 0.05 and 0.95 quantile, the interval range would be 90. The interval range corresponds to  $(100-\alpha)/100$ , where  $\alpha$  is the decimal value that indicates how much is outside

the prediction interval (see e.g. Gneiting and Raftery (2007)).

weigh Logical. If TRUE (the default), weigh the score by  $\alpha/2$ , so it can be averaged into

an interval score that, in the limit (for an increasing number of equally spaced quantiles/prediction intervals), corresponds to the CRPS.  $\alpha$  is the value that corresponds to the  $(\alpha/2)$  or  $(1 - \alpha/2)$ , i.e. it is the decimal value that represents how much is outside a central prediction interval (E.g. for a 90 percent central

prediction interval, alpha is 0.1).

separate\_results

Logical. If TRUE (default is FALSE), then the separate parts of the interval score (dispersion penalty, penalties for over- and under-prediction get returned as separate elements of a list). If you want a data.frame instead, simply call

as.data.frame() on the output.

# Value

Vector with the scoring values, or a list with separate entries if separate\_results is TRUE.

)
```

is\_forecast\_binary

Test whether an object is a forecast object

## **Description**

Test whether an object is a forecast object.

You can test for a specific forecast\_<type> class using the appropriate is\_forecast\_<type> function.

```
is_forecast_binary(x)
is_forecast_nominal(x)
is_forecast_ordinal(x)
is_forecast_point(x)
is_forecast_quantile(x)
```

70 logs\_categorical

```
is_forecast_sample(x)
is_forecast(x)
```

### **Arguments**

Χ

An R object.

#### Value

is\_forecast: TRUE if the object is of class forecast, FALSE otherwise.

is\_forecast\_<type>\*: TRUE if the object is of class forecast\_\* in addition to class forecast,
FALSE otherwise.

### **Examples**

```
forecast_binary <- as_forecast_binary(example_binary)
is_forecast(forecast_binary)</pre>
```

logs\_categorical

Log score for categorical outcomes

# Description

### Log score for categorical (nominal or ordinal) outcomes

The Log Score is the negative logarithm of the probability assigned to the observed value. It is a proper scoring rule. Small values are better (best is zero, worst is infinity).

# Usage

```
logs_categorical(observed, predicted, predicted_label)
```

### **Arguments**

observed

Factor of length n with N levels holding the observed values.

predicted

nxN matrix of predictive probabilities, n (number of rows) being the number of

observations and N (number of columns) the number of possible outcomes.

predicted\_label

Factor of length N, denoting the outcome that the probabilities in predicted

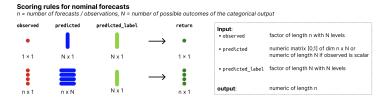

correspond to.

### Value

A numeric vector of size n with log scores

logs\_sample 71

## **Input format**

#### See Also

Other log score functions: logs\_sample(), scoring-functions-binary

## **Examples**

```
factor_levels <- c("one", "two", "three")
predicted_label <- factor(c("one", "two", "three"), levels = factor_levels)
observed <- factor(c("one", "three", "two"), levels = factor_levels)
predicted <- matrix(
    c(0.8, 0.1, 0.1,
        0.1, 0.2, 0.7,
        0.4, 0.4, 0.2),
    nrow = 3,
    byrow = TRUE
)
logs_categorical(observed, predicted, predicted_label)</pre>
```

logs\_sample

Logarithmic score (sample-based version)

## **Description**

This function is a wrapper around the logs\_sample() function from the scoringRules package.

The log score is the negative logarithm of the predictive density evaluated at the observed value.

The function should be used to score continuous predictions only. While the Log Score is in theory also applicable to discrete forecasts, the problem lies in the implementation: The function uses a kernel density estimation, which is not well defined with integer-valued Monte Carlo Samples. See the scoringRules package for more details and alternatives, e.g. calculating scores for specific discrete probability distributions.

```
logs_sample(observed, predicted, ...)
```

72 log\_shift

# **Arguments**

observed A vector with observed values of size n

predicted nxN matrix of predictive samples, n (number of rows) being the number of data

points and N (number of columns) the number of Monte Carlo samples. Alter-

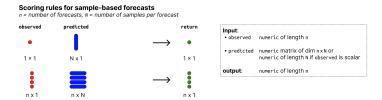

natively, predicted can just be a vector of size n.

... Additional arguments passed to logs\_sample() from the scoringRules package.

#### Value

Vector with scores.

## **Input format**

#### References

Alexander Jordan, Fabian Krüger, Sebastian Lerch, Evaluating Probabilistic Forecasts with scoringRules, https://www.jstatsoft.org/article/view/v090i12

# See Also

Other log score functions: logs\_categorical(), scoring-functions-binary

## **Examples**

```
observed <- rpois(30, lambda = 1:30)
predicted <- replicate(200, rpois(n = 30, lambda = 1:30))
logs_sample(observed, predicted)</pre>
```

log\_shift

Log transformation with an additive shift

### **Description**

Function that shifts a value by some offset and then applies the natural logarithm to it.

```
log\_shift(x, offset = 0, base = exp(1))
```

mad\_sample 73

# **Arguments**

x vector of input values to be transformed

offset Number to add to the input value before taking the natural logarithm.

base A positive number: the base with respect to which logarithms are computed.

Defaults to e = exp(1).

# **Details**

The output is computed as log(x + offset)

#### Value

A numeric vector with transformed values

#### References

Transformation of forecasts for evaluating predictive performance in an epidemiological context Nikos I. Bosse, Sam Abbott, Anne Cori, Edwin van Leeuwen, Johannes Bracher, Sebastian Funk medRxiv 2023.01.23.23284722 doi:10.1101/2023.01.23.23284722 https://www.medrxiv.org/content/10.1101/2023.01.23.23284722v1 # nolint

# **Examples**

```
library(magrittr) # pipe operator
log_shift(1:10)
log_shift(0:9, offset = 1)

example_quantile[observed > 0, ] %>%
    as_forecast_quantile() %>%
    transform_forecasts(fun = log_shift, offset = 1)
```

mad\_sample

Determine dispersion of a probabilistic forecast

# **Description**

Sharpness is the ability of the model to generate predictions within a narrow range and dispersion is the lack thereof. It is a data-independent measure, and is purely a feature of the forecasts themselves.

Dispersion of predictive samples corresponding to one single observed value is measured as the normalised median of the absolute deviation from the median of the predictive samples. For details, see mad() and the explanations given in Funk et al. (2019)

# Usage

```
mad_sample(observed = NULL, predicted, ...)
```

# **Arguments**

observed Place holder, argument will be ignored and exists only for consistency with other

scoring functions. The output does not depend on any observed values.

predicted nxN matrix of predictive samples, n (number of rows) being the number of data

points and N (number of columns) the number of Monte Carlo samples. Alter-

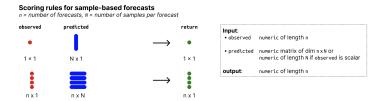

natively, predicted can just be a vector of size n.

... Additional arguments passed to mad().

# Value

Vector with dispersion values.

# **Input format**

# References

# **Examples**

```
predicted <- replicate(200, rpois(n = 30, lambda = 1:30))
mad_sample(predicted = predicted)</pre>
```

pit\_histogram\_sample Probability integral transformation for counts

# Description

Uses a Probability integral transformation (PIT) (or a randomised PIT for integer forecasts) to assess the calibration of predictive Monte Carlo samples.

pit\_histogram\_sample 75

# Usage

```
pit_histogram_sample(
  observed,
  predicted,
  quantiles,
  integers = c("nonrandom", "random", "ignore"),
  n_replicates = NULL
)
```

# Arguments

observed A vector with observed values of size n

predicted nxN matrix of predictive samples, n (number of rows) being the number of data

points and N (number of columns) the number of Monte Carlo samples. Alter-

natively, predicted can just be a vector of size n.

quantiles A vector of quantiles between which to calculate the PIT.

integers How to handle integer forecasts (count data). This is based on methods de-

scribed Czado et al. (2007). If "nonrandom" (default) the function will use the non-randomised PIT method. If "random", will use the randomised PIT method.

If "ignore", will treat integer forecasts as if they were continuous.

n\_replicates The number of draws for the randomised PIT for discrete predictions. Will be

ignored if forecasts are continuous or integers is not set to random.

#### **Details**

Calibration or reliability of forecasts is the ability of a model to correctly identify its own uncertainty in making predictions. In a model with perfect calibration, the observed data at each time point look as if they came from the predictive probability distribution at that time.

Equivalently, one can inspect the probability integral transform of the predictive distribution at time t.

$$u_t = F_t(x_t)$$

where  $x_t$  is the observed data point at time t in  $t_1, \ldots, t_n$ , n being the number of forecasts, and  $F_t$  is the (continuous) predictive cumulative probability distribution at time t. If the true probability distribution of outcomes at time t is  $G_t$  then the forecasts  $F_t$  are said to be ideal if  $F_t = G_t$  at all times t. In that case, the probabilities  $u_t$  are distributed uniformly.

In the case of discrete nonnegative outcomes such as incidence counts, the PIT is no longer uniform even when forecasts are ideal. In that case two methods are available ase described by Czado et al. (2007).

By default, a nonrandomised PIT is calculated using the conditional cumulative distribution function

$$F(u) = \begin{cases} 0 & \text{if } v < P_t(k_t - 1) \\ (v - P_t(k_t - 1)) / (P_t(k_t) - P_t(k_t - 1)) & \text{if } P_t(k_t - 1) \le v < P_t(k_t) \\ 1 & \text{if } v \ge P_t(k_t) \end{cases}$$

where  $k_t$  is the observed count,  $P_t(x)$  is the predictive cumulative probability of observing incidence k at time t and  $P_t(-1) = 0$  by definition. Values of the PIT histogram are then created by averaging over the n predictions,

$$\bar{F}(u) = \frac{i=1}{n} \sum_{i=1}^{n} F^{(i)}(u)$$

And calculating the value at each bin between quantile  $q_i$  and quantile  $q_{i+1}$  as

$$\bar{F}(q_i) - \bar{F}(q_{i+1})$$

Alternatively, a randomised PIT can be used instead. In this case, the PIT is

$$u_t = P_t(k_t) + v * (P_t(k_t) - P_t(k_t - 1))$$

where v is standard uniform and independent of k. The values of the PIT histogram are then calculated by binning the  $u_t$  values as above.

#### Value

A vector with PIT histogram densities for the bins corresponding to the given quantiles.

plot\_correlations

Plot correlation between metrics

# **Description**

Plots a heatmap of correlations between different metrics.

# Usage

```
plot_correlations(correlations, digits = NULL)
```

# **Arguments**

correlations A data.table of correlations between scores as produced by get\_correlations().

digits A number indicating how many decimal places the correlations should be rounded

to. By default (digits = NULL) no rounding takes place.

# Value

A ggplot object showing a coloured matrix of correlations between metrics.

A ggplot object with a visualisation of correlations between metrics

```
library(magrittr) # pipe operator
scores <- example_quantile %>%
   as_forecast_quantile %>%
   score()
correlations <- scores %>%
   summarise_scores() %>%
   get_correlations()
plot_correlations(correlations, digits = 2)
```

78 plot\_forecast\_counts

# **Description**

Visualise Where Forecasts Are Available.

# Usage

```
plot_forecast_counts(
  forecast_counts,
    x,
    y = "model",
    x_as_factor = TRUE,
    show_counts = TRUE
)
```

# Arguments

forecast\_counts

A data.table (or similar) with a column count holding forecast counts, as produced by get\_forecast\_counts().

x Character vector of length one that denotes the name of the column to appear on

the x-axis of the plot.

y Character vector of length one that denotes the name of the column to appear on

the y-axis of the plot. Default is "model".

x\_as\_factor Logical (default is TRUE). Whether or not to convert the variable on the x-axis to

a factor. This has an effect e.g. if dates are shown on the x-axis.

show\_counts Logical (default is TRUE) that indicates whether or not to show the actual count

numbers on the plot.

# Value

A ggplot object with a plot of forecast counts

```
library(ggplot2)
library(magrittr) # pipe operator
forecast_counts <- example_quantile %>%
    as_forecast_quantile %>%
    get_forecast_counts(by = c("model", "target_type", "target_end_date"))
plot_forecast_counts(
    forecast_counts, x = "target_end_date", show_counts = FALSE
) +
    facet_wrap("target_type")
```

plot\_heatmap 79

# Description

This function can be used to create a heatmap of one metric across different groups, e.g. the interval score obtained by several forecasting models in different locations.

# Usage

```
plot_heatmap(scores, y = "model", x, metric)
```

# **Arguments**

scores	A data.frame of scores based on quantile forecasts as produced by score().
У	The variable from the scores you want to show on the y-Axis. The default for this is "model"
x	The variable from the scores you want to show on the x-Axis. This could be something like "horizon", or "location"
metric	String, the metric that determines the value and colour shown in the tiles of the heatmap.

# Value

A ggplot object showing a heatmap of the desired metric

```
library(magrittr) # pipe operator
scores <- example_quantile %>%
    as_forecast_quantile %>%
    score()
scores <- summarise_scores(scores, by = c("model", "target_type"))
scores <- summarise_scores(
    scores, by = c("model", "target_type"),
    fun = signif, digits = 2
)
plot_heatmap(scores, x = "target_type", metric = "bias")</pre>
```

```
plot_interval_coverage
```

Plot interval coverage

# **Description**

Plot interval coverage values (see get\_coverage() for more information).

# Usage

```
plot_interval_coverage(coverage, colour = "model")
```

# Arguments

coverage A data frame of coverage values as produced by get\_coverage().

colour According to which variable shall the graphs be coloured? Default is "model".

# Value

ggplot object with a plot of interval coverage

# **Examples**

```
example <- as_forecast_quantile(example_quantile)
coverage <- get_coverage(example, by = "model")
plot_interval_coverage(coverage)</pre>
```

```
plot_pairwise_comparisons
```

Plot heatmap of pairwise comparisons

# Description

Creates a heatmap of the ratios or pvalues from a pairwise comparison between models.

# Usage

```
plot_pairwise_comparisons(
  comparison_result,
  type = c("mean_scores_ratio", "pval")
)
```

plot\_quantile\_coverage

# **Arguments**

comparison\_result

A data.frame as produced by get\_pairwise\_comparisons().

type

Character vector of length one that is either "mean\_scores\_ratio" or "pval". This denotes whether to visualise the ratio or the p-value of the pairwise comparison.

81

Default is "mean\_scores\_ratio".

#### Value

A ggplot object with a heatmap of mean score ratios from pairwise comparisons.

# **Examples**

```
library(ggplot2)
library(magrittr) # pipe operator
scores <- example_quantile %>%
    as_forecast_quantile %>%
    score()
pairwise <- get_pairwise_comparisons(scores, by = "target_type")
plot_pairwise_comparisons(pairwise, type = "mean_scores_ratio") +
    facet_wrap(~target_type)</pre>
```

```
plot_quantile_coverage
```

Plot quantile coverage

# **Description**

Plot quantile coverage values (see get\_coverage() for more information).

# Usage

```
plot_quantile_coverage(coverage, colour = "model")
```

# **Arguments**

coverage A data frame of coverage values as produced by get\_coverage().

colour String, according to which variable shall the graphs be coloured? Default is

"model".

#### Value

A ggplot object with a plot of interval coverage

```
example <- as_forecast_quantile(example_quantile)
coverage <- get_coverage(example, by = "model")
plot_quantile_coverage(coverage)</pre>
```

82 plot\_wis

plot\_wis

Plot contributions to the weighted interval score

# **Description**

Visualise the components of the weighted interval score: penalties for over-prediction, underprediction and for high dispersion (lack of sharpness).

# Usage

```
plot_wis(scores, x = "model", relative_contributions = FALSE, flip = FALSE)
```

# **Arguments**

A data.table of scores based on quantile forecasts as produced by score() and summarised using summarise\_scores().

X The variable from the scores you want to show on the x-Axis. Usually this will be "model".

relative\_contributions

Logical. Show relative contributions instead of absolute contributions? Default is FALSE and this functionality is not available yet.

flip Boolean (default is FALSE), whether or not to flip the axes.

#### Value

A ggplot object showing a contributions from the three components of the weighted interval score. A ggplot object with a visualisation of the WIS decomposition

# References

Bracher J, Ray E, Gneiting T, Reich, N (2020) Evaluating epidemic forecasts in an interval format. https://journals.plos.org/ploscompbiol/article?id=10.1371/journal.pcbi.1008618

```
library(ggplot2)
library(magrittr) # pipe operator
scores <- example_quantile %>%
    as_forecast_quantile %>%
    score()
scores <- summarise_scores(scores, by = c("model", "target_type"))
plot_wis(scores,
    x = "model",
    relative_contributions = TRUE
) +
    facet_wrap(~target_type)
plot_wis(scores,</pre>
```

print.forecast 83

```
x = "model",
relative_contributions = FALSE
) +
facet_wrap(~target_type, scales = "free_x")
```

print.forecast

Print information about a forecast object

# **Description**

This function prints information about a forecast object, including "Forecast type", "Score columns", "Forecast unit".

# Usage

```
## S3 method for class 'forecast'
print(x, ...)
```

# **Arguments**

x A forecast object

... Additional arguments for print().

## Value

Returns x invisibly.

# Examples

```
dat <- as_forecast_quantile(example_quantile)
print(dat)</pre>
```

quantile\_score

Quantile score

# Description

Proper Scoring Rule to score quantile predictions. Smaller values are better. The quantile score is closely related to the interval score (see wis()) and is the quantile equivalent that works with single quantiles instead of central prediction intervals.

The quantile score, also called pinball loss, for a single quantile level au is defined as

$$\operatorname{QS}_{\tau}(F,y) = 2 \cdot \left\{ \mathbf{1}(y \leq q_{\tau}) - \tau \right\} \cdot (q_{\tau} - y) = \begin{cases} 2 \cdot (1 - \tau) * q_{\tau} - y, & \text{if } y \leq q_{\tau} \\ 2 \cdot \tau * |q_{\tau} - y|, & \text{if } y > q_{\tau}, \end{cases}$$

with  $q_{\tau}$  being the  $\tau$ -quantile of the predictive distribution F, and  $\mathbf{1}(\cdot)$  the indicator function.

84 quantile\_score

The weighted interval score for a single prediction interval can be obtained as the average of the quantile scores for the lower and upper quantile of that prediction interval:

$$\mathrm{WIS}_{\alpha}(F,y) = \frac{\mathrm{QS}_{\alpha/2}(F,y) + \mathrm{QS}_{1-\alpha/2}(F,y)}{2}.$$

See the SI of Bracher et al. (2021) for more details.

quantile\_score() returns the average quantile score across the quantile levels provided. For a set of quantile levels that form pairwise central prediction intervals, the quantile score is equivalent to the interval score.

# Usage

quantile\_score(observed, predicted, quantile\_level, weigh = TRUE)

#### **Arguments**

observed Numeric vector of size n with the observed values.

predicted Numeric nxN matrix of predictive quantiles, n (number of rows) being the num-

ber of forecasts (corresponding to the number of observed values) and N (number of columns) the number of quantiles per forecast. If observed is just a single

number, then predicted can just be a vector of size N.

quantile\_level Vector of of size N with the quantile levels for which predictions were made.

weigh Logical. If TRUE (the default), weigh the score by  $\alpha/2$ , so it can be averaged into

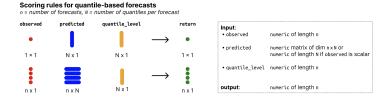

an interval score that, in the limit (for an increasing number of equally spaced quantiles/prediction intervals), corresponds to the CRPS.  $\alpha$  is the value that corresponds to the  $(\alpha/2)$  or  $(1 - \alpha/2)$ , i.e. it is the decimal value that represents how much is outside a central prediction interval (E.g. for a 90 percent central

prediction interval, alpha is 0.1).

#### Value

Numeric vector of length n with the quantile score. The scores are averaged across quantile levels if multiple quantile levels are provided (the result of calling rowMeans() on the matrix of quantile scores that is computed based on the observed and predicted values).

# **Input format**

rps\_ordinal 85

# **Examples**

```
observed <- rnorm(10, mean = 1:10)
alpha <- 0.5
lower <- qnorm(alpha / 2, observed)</pre>
upper <- qnorm((1 - alpha / 2), observed)</pre>
qs_lower <- quantile_score(observed,</pre>
 predicted = matrix(lower),
 quantile_level = alpha / 2
)
qs_upper <- quantile_score(observed,</pre>
 predicted = matrix(upper),
 quantile_level = 1 - alpha / 2
)
interval_score <- (qs_lower + qs_upper) / 2</pre>
interval_score2 <- quantile_score(</pre>
 observed,
 predicted = cbind(lower, upper),
 quantile_level = c(alpha / 2, 1 - alpha / 2)
)
# this is the same as the following
wis(
 observed,
 predicted = cbind(lower, upper),
 quantile_level = c(alpha / 2, 1 - alpha / 2)
)
```

rps\_ordinal

Ranked Probability Score for ordinal outcomes

# Description

The Ranked Probability Score (RPS) measures the difference between the predicted and observed cumulative distribution functions. It is a proper scoring rule that takes the ordering of categories into account. Small values are better (best is zero, worst is N - 1 where N is the number of categories).

# Usage

```
rps_ordinal(observed, predicted_label)
```

# **Arguments**

observed A factor of length n with N levels holding the observed values.

predicted nxN matrix of predictive probabilities, n (number of rows) being the number of

observations and N (number of columns) the number of possible outcomes.

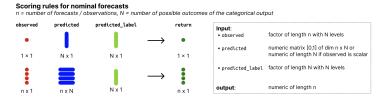

predicted\_label

A factor of length N, denoting the outcome that the probabilities in predicted correspond to.

#### Value

A numeric vector of size n with ranked probability scores

# **Input format**

# **Examples**

```
factor_levels <- c("one", "two", "three")
predicted_label <- factor(factor_levels, levels = factor_levels, ordered = TRUE)
observed <- factor(c("three", "three", "two"), levels = factor_levels, ordered = TRUE)
predicted <- matrix(
    c(0.8, 0.1, 0.1,
        0.1, 0.2, 0.7,
        0.4, 0.4, 0.2),
    nrow = 3,
    byrow = TRUE
)
rps_ordinal(observed, predicted, predicted_label)</pre>
```

score.forecast\_binary Evaluate forecasts

# **Description**

score() applies a selection of scoring metrics to a forecast object. score() is a generic that dispatches to different methods depending on the class of the input data.

See as\_forecast\_binary(), as\_forecast\_quantile() etc. for information on how to create a forecast object.

See get\_forecast\_unit() for more information on the concept of a forecast unit.

For additional help and examples, check out the paper Evaluating Forecasts with scoringutils in R.

score.forecast\_binary 87

# Usage

```
## S3 method for class 'forecast_binary'
score(forecast, metrics = get_metrics(forecast), ...)
## S3 method for class 'forecast_nominal'
score(forecast, metrics = get_metrics(forecast), ...)
## S3 method for class 'forecast_ordinal'
score(forecast, metrics = get_metrics(forecast), ...)
## S3 method for class 'forecast_point'
score(forecast, metrics = get_metrics(forecast), ...)
## S3 method for class 'forecast_quantile'
score(forecast, metrics = get_metrics(forecast), ...)
## S3 method for class 'forecast_sample'
score(forecast, metrics = get_metrics(forecast), ...)
score(forecast, metrics = get_metrics(forecast), ...)
```

# Arguments

forecast A forecast object (a validated data.table with predicted and observed values).

Metrics A named list of scoring functions. Names will be used as column names in the output. See <a href="mailto:get\_metrics">get\_metrics</a>() for more information on the default metrics used. See the <a href="mailto:Customising metrics">Customising metrics</a> section below for information on how to pass custom arguments to scoring functions.

... Currently unused. You <a href="mailto:cannot">cannot</a> pass additional arguments to scoring functions

via .... See the *Customising metrics* section below for details on how to use purrr::partial() to pass arguments to individual metrics.

#### **Details**

# **Customising metrics**

If you want to pass arguments to a scoring function, you need change the scoring function itself via e.g. purrr::partial() and pass an updated list of functions with your custom metric to the metrics argument in score(). For example, to use interval\_coverage() with interval\_range = 90, you would define a new function, e.g. interval\_coverage\_90 <- purrr::partial(interval\_coverage, interval\_range = 90) and pass this new function to metrics in score().

Note that if you want to pass a variable as an argument, you can unquote it with !! to make sure the value is evaluated only once when the function is created. Consider the following example:

```
custom_arg <- "foo"
print1 <- purrr::partial(print, x = custom_arg)
print2 <- purrr::partial(print, x = !!custom_arg)</pre>
```

```
custom_arg <- "bar"
print1() # prints 'bar'
print2() # prints 'foo'</pre>
```

#### Value

An object of class scores. This object is a data.table with unsummarised scores (one score per forecast) and has an additional attribute metrics with the names of the metrics used for scoring. See <a href="mailto:summarise\_scores">summarise\_scores</a>()) for information on how to summarise scores.

scoring-functions-binary

Metrics for binary outcomes

# **Description**

# **Brier score**

The Brier Score is the mean squared error between the probabilistic prediction and the observed outcome. The Brier score is a proper scoring rule. Small values are better (best is 0, the worst is 1).

$$Brier\_Score = (prediction - outcome)^2$$
,

where outcome  $\in \{0, 1\}$ , and prediction  $\in [0, 1]$  represents the probability that the outcome is equal to 1.

#### Log score for binary outcomes

The Log Score is the negative logarithm of the probability assigned to the observed value. It is a proper scoring rule. Small values are better (best is zero, worst is infinity).

# Usage

```
brier_score(observed, predicted)
```

logs\_binary(observed, predicted)

# **Arguments**

observed A factor of length n with exactly two levels, holding the observed values. The

highest factor level is assumed to be the reference level. This means that predicted represents the probability that the observed value is equal to the highest factor

level.

predicted A numeric vector of length n, holding probabilities. Values represent the prob-

ability that the corresponding outcome is equal to the highest level of the factor

observed.

## Details

The functions require users to provide observed values as a factor in order to distinguish its input from the input format required for scoring point forecasts. Internally, however, factors will be converted to numeric values. A factor observed = factor(c(0, 1, 1, 0, 1)) with two levels (0 and 1) would internally be coerced to a numeric vector (in this case this would result in the numeric vector c(1, 2, 2, 1, 1)). After subtracting 1, the resulting vector (c(0, 1, 1, 0)) in this case) is used for internal calculations. All predictions are assumed represent the probability that the outcome is equal of the last/highest factor level (in this case that the outcome is equal to 1).

You could alternatively also provide a vector like observed = factor(c("a", "b", "b", "a")) (with two levels, a and b), which would result in exactly the same internal representation. Probabilities then represent the probability that the outcome is equal to "b". If you want your predictions

90 select\_metrics

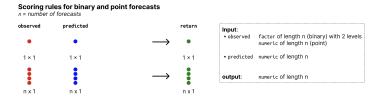

to be probabilities that the outcome is "a", then you could of course make observed a factor with levels swapped, i.e. observed = factor(c("a", "b", "a"), levels = c("b", "a"))

# Value

A numeric vector of size n with the Brier scores

A numeric vector of size n with log scores

# **Input format**

# See Also

Other log score functions: logs\_categorical(), logs\_sample()

# **Examples**

```
observed <- factor(sample(c(0, 1), size = 30, replace = TRUE))
predicted <- runif(n = 30, min = 0, max = 1)

brier_score(observed, predicted)
logs_binary(observed, predicted)</pre>
```

select\_metrics

Select metrics from a list of functions

# Description

Helper function to return only the scoring rules selected by the user from a list of possible functions.

# Usage

```
select_metrics(metrics, select = NULL, exclude = NULL)
```

# Arguments

metrics	A list of scoring functions.
select	A character vector of scoring rules to select from the list. If select is NULL (the default), all possible scoring rules are returned.
exclude	A character vector of scoring rules to exclude from the list. If select is not NULL, this argument is ignored.

set\_forecast\_unit 91

#### Value

A list of scoring functions.

# **Examples**

```
select_metrics(
  metrics = get_metrics(example_binary),
  select = "brier_score"
)
select_metrics(
  metrics = get_metrics(example_binary),
  exclude = "log_score"
)
```

set\_forecast\_unit

Set unit of a single forecast manually

# **Description**

Helper function to set the unit of a single forecast (i.e. the combination of columns that uniquely define a single forecast) manually. This simple function keeps the columns specified in forecast\_unit (plus additional protected columns, e.g. for observed values, predictions or quantile levels) and removes duplicate rows. set\_forecast\_unit() will mainly be called when constructing a forecast object via the forecast\_unit argument in as\_forecast\_<type>.

If not done explicitly, scoringutils attempts to determine the unit of a single forecast automatically by simply assuming that all column names are relevant to determine the forecast unit. This may lead to unexpected behaviour, so setting the forecast unit explicitly can help make the code easier to debug and easier to read.

# Usage

```
set_forecast_unit(data, forecast_unit)
```

# **Arguments**

data A data.frame (or similar) with predicted and observed values. See the details

section of for additional information on the required input format.

forecast\_unit Character vector with the names of the columns that uniquely identify a single

forecast.

## Value

A data.table with only those columns kept that are relevant to scoring or denote the unit of a single forecast as specified by the user.

92 se\_mean\_sample

# **Examples**

```
library(magrittr) # pipe operator
example_quantile %>%
    scoringutils:::set_forecast_unit(
        c("location", "target_end_date", "target_type", "horizon", "model")
)
```

se\_mean\_sample

Squared error of the mean (sample-based version)

# **Description**

Squared error of the mean calculated as

 $mean(observed - mean prediction)^2$ 

The mean prediction is calculated as the mean of the predictive samples.

# Usage

```
se_mean_sample(observed, predicted)
```

# **Arguments**

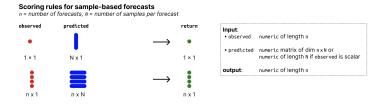

observed

A vector with observed values of size n

predicted

nxN matrix of predictive samples, n (number of rows) being the number of data points and N (number of columns) the number of Monte Carlo samples. Alternatively, predicted can just be a vector of size n.

# **Input format**

```
observed <- rnorm(30, mean = 1:30)
predicted_values <- matrix(rnorm(30, mean = 1:30))
se_mean_sample(observed, predicted_values)</pre>
```

summarise\_scores 93

summarise\_scores

Summarise scores as produced by score()

# **Description**

Summarise scores as produced by score().

summarise\_scores relies on a way to identify the names of the scores and distinguish them from columns that denote the unit of a single forecast. Internally, this is done via a stored attribute, metrics that stores the names of the scores. This means, however, that you need to be careful with renaming scores after they have been produced by score(). If you do, you also have to manually update the attribute by calling attr(scores, "metrics") <- new\_names.

# Usage

```
summarise_scores(scores, by = "model", fun = mean, ...)
summarize_scores(scores, by = "model", fun = mean, ...)
```

# **Arguments**

scores	An object of class scores (a data.table with scores and an additional attribute metrics as produced by score()).
by	Character vector with column names to summarise scores by. Default is "model", i.e. scores are summarised by the "model" column.
fun	A function used for summarising scores. Default is mean().
	Additional parameters that can be passed to the summary function provided to fun. For more information see the documentation of the respective function.

#### Value

A data.table with summarised scores. Scores are summarised according to the names of the columns of the original data specified in by using the fun passed to summarise\_scores().

```
library(magrittr) # pipe operator
scores <- example_sample_continuous %>%
    as_forecast_sample() %>%
    score()

# get scores by model
summarise_scores(scores, by = "model")

# get scores by model and target type
summarise_scores(scores, by = c("model", "target_type"))

# get standard deviation
```

94 test\_columns\_present

```
summarise_scores(scores, by = "model", fun = sd)
# round digits
summarise_scores(scores, by = "model") %>%
summarise_scores(fun = signif, digits = 2)
```

```
test_columns_not_present
```

Test whether column names are NOT present in a data.frame

# Description

The function checks whether all column names are NOT present. If none of the columns are present, the function returns TRUE. If one or more columns are present, the function returns FALSE.

# Usage

```
test_columns_not_present(data, columns)
```

# Arguments

data A data.frame or similar to be checked

columns A character vector of column names to check

# Value

Returns TRUE if none of the columns are present and FALSE otherwise

# Description

The function checks whether all column names are present. If one or more columns are missing, the function returns FALSE. If all columns are present, the function returns TRUE.

# Usage

```
test_columns_present(data, columns)
```

# **Arguments**

data A data.frame or similar to be checked

columns A character vector of column names to check

# Value

Returns TRUE if all columns are present and FALSE otherwise

theme\_scoringutils 95

theme\_scoringutils

Scoringutils ggplot2 theme

# Description

A theme for ggplot2 plots used in scoringutils.

# Usage

```
theme_scoringutils()
```

#### Value

A ggplot2 theme

transform\_forecasts

Transform forecasts and observed values

# **Description**

Function to transform forecasts and observed values before scoring.

# Usage

```
transform_forecasts(
  forecast,
  fun = log_shift,
  append = TRUE,
  label = "log",
   ...
)
```

# **Arguments**

forecast

A forecast object (a validated data.table with predicted and observed values).

fun

A function used to transform both observed values and predictions. The default function is <code>log\_shift()</code>, a custom function that is essentially the same as <code>log()</code>, but has an additional arguments (offset) that allows you add an offset before applying the logarithm. This is often helpful as the natural log transformation is not defined at zero. A common, and pragmatic solution, is to add a small offset to the data before applying the log transformation. In our work we have often used an offset of 1 but the precise value will depend on your application.

96 transform\_forecasts

append	Logical, defaults to TRUE. Whether or not to append a transformed version of the data to the currently existing data (TRUE). If selected, the data gets transformed
	and appended to the existing data, making it possible to use the outcome directly in score(). An additional column, 'scale', gets created that denotes which rows or untransformed ('scale' has the value "natural") and which have been transformed ('scale' has the value passed to the argument label).
label	A string for the newly created 'scale' column to denote the newly transformed values. Only relevant if append = TRUE.
• • •	Additional parameters to pass to the function you supplied. For the default option of log_shift() this could be the offset argument.

#### **Details**

There are a few reasons, depending on the circumstances, for why this might be desirable (check out the linked reference for more info). In epidemiology, for example, it may be useful to log-transform incidence counts before evaluating forecasts using scores such as the weighted interval score (WIS) or the continuous ranked probability score (CRPS). Log-transforming forecasts and observations changes the interpretation of the score from a measure of absolute distance between forecast and observation to a score that evaluates a forecast of the exponential growth rate. Another motivation can be to apply a variance-stabilising transformation or to standardise incidence counts by population.

Note that if you want to apply a transformation, it is important to transform the forecasts and observations and then apply the score. Applying a transformation after the score risks losing propriety of the proper scoring rule.

# Value

A forecast object with either a transformed version of the data, or one with both the untransformed and the transformed data. includes the original data as well as a transformation of the original data. There will be one additional column, 'scale', present which will be set to "natural" for the untransformed forecasts.

```

validate\_metrics

Validate metrics

# Description

This function validates whether the list of metrics is a list of valid functions.

The function is used in score() to make sure that all metrics are valid functions.

#### **Usage**

validate\_metrics(metrics)

#### **Arguments**

metrics

A named list with metrics. Every element should be a scoring function to be applied to the data.

#### Value

A named list of metrics, with those filtered out that are not valid functions

wis

Weighted interval score (WIS)

# **Description**

The WIS is a proper scoring rule used to evaluate forecasts in an interval- / quantile-based format. See Bracher et al. (2021). Smaller values are better.

As the name suggest the score assumes that a forecast comes in the form of one or multiple central prediction intervals. A prediction interval is characterised by a lower and an upper bound formed by a pair of predictive quantiles. For example, a 50% central prediction interval is formed by the 0.25 and 0.75 quantiles of the predictive distribution.

# Interval score

The interval score (IS) is the sum of three components: overprediction, underprediction and dispersion. For a single prediction interval only one of the components is non-zero. If for a single prediction interval the observed value is below the lower bound, then the interval score is equal to the absolute difference between the lower bound and the observed value ("underprediction"). "Overprediction" is defined analogously. If the observed value falls within the bounds of the prediction interval, then the interval score is equal to the width of the prediction interval, i.e. the difference between the upper and lower bound. For a single interval, we therefore have:

$$IS = (upper-lower) + \frac{2}{\alpha}(lower-observed) * \mathbf{1}(observed < lower) + \frac{2}{\alpha}(observed-upper) * \mathbf{1}(observed > upper)$$

where  $\mathbf{1}()$  is the indicator function and indicates how much is outside the prediction interval.  $\alpha$  is the decimal value that indicates how much is outside the prediction interval. For a 90% prediction interval, for example,  $\alpha$  is equal to 0.1. No specific distribution is assumed, but the interval formed by the quantiles has to be symmetric around the median (i.e you can't use the 0.1 quantile as the lower bound and the 0.7 quantile as the upper bound). Non-symmetric quantiles can be scored using the function quantile\_score().

For a set of k = 1, ..., K prediction intervals and the median m, we can compute a weighted interval score (WIS) as the sum of the interval scores for individual intervals:

$$\mathrm{WIS}_{\alpha_{\{0:K\}}}(F,y) = \frac{1}{K+1/2} \times \left( w_0 \times |y-m| + \sum_{k=1}^K \left\{ w_k \times \mathrm{IS}_{\alpha_k}(F,y) \right\} \right)$$

The individual scores are usually weighted with  $w_k = \frac{\alpha_k}{2}$ . This weight ensures that for an increasing number of equally spaced quantiles, the WIS converges to the continuous ranked probability score (CRPS).

#### Quantile score

In addition to the interval score, there also exists a quantile score (QS) (see quantile\_score()), which is equal to the so-called pinball loss. The quantile score can be computed for a single quantile (whereas the interval score requires two quantiles that form an interval). However, the intuitive decomposition into overprediction, underprediction and dispersion does not exist for the quantile score.

# Two versions of the weighted interval score

There are two ways to conceptualise the weighted interval score across several quantiles / prediction intervals and the median.

In one view, you would treat the WIS as the average of quantile scores (and the median as 0.5-quantile) (this is the default for wis()). In another view, you would treat the WIS as the average of several interval scores + the difference between the observed value and median forecast. The effect of that is that in contrast to the first view, the median has twice as much weight (because it is weighted like a prediction interval, rather than like a single quantile). Both are valid ways to conceptualise the WIS and you can control the behaviour with the count\_median\_twice-argument.

**WIS components**: WIS components can be computed individually using the functions overprediction, underprediction, and dispersion.

# Usage

```
wis(
  observed,
  predicted,
  quantile_level,
  separate_results = FALSE,
  weigh = TRUE,
  count_median_twice = FALSE,
  na.rm = FALSE
)

dispersion_quantile(observed, predicted, quantile_level, ...)

overprediction_quantile(observed, predicted, quantile_level, ...)

underprediction_quantile(observed, predicted, quantile_level, ...)
```

# **Arguments**

observed Numeric vector of size n with the observed values.

predicted Numeric nxN matrix of predictive quantiles, n (number of rows) being the num-

ber of forecasts (corresponding to the number of observed values) and N (number of columns) the number of quantiles per forecast. If observed is just a single

number, then predicted can just be a vector of size N.

quantile\_level Vector of of size N with the quantile levels for which predictions were made.

separate\_results

Logical. If TRUE (default is FALSE), then the separate parts of the interval score (dispersion penalty, penalties for over- and under-prediction get returned as separate elements of a list). If you want a data.frame instead, simply call as.data.frame() on the output.

weigh

Logical. If TRUE (the default), weigh the score by  $\alpha/2$ , so it can be averaged into an interval score that, in the limit (for an increasing number of equally spaced quantiles/prediction intervals), corresponds to the CRPS.  $\alpha$  is the value that corresponds to the  $(\alpha/2)$  or  $(1-\alpha/2)$ , i.e. it is the decimal value that represents how much is outside a central prediction interval (E.g. for a 90 percent central prediction interval, alpha is 0.1).

count\_median\_twice

If TRUE, count the median twice in the score.

na.rm If TRUE, ignore NA values when computing the score.

Additional arguments passed on to wis() from functions overprediction\_quantile(), underprediction\_quantile() and dispersion\_quantile().

#### Value

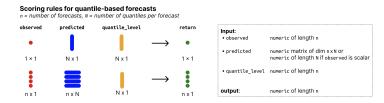

wis(): a numeric vector with WIS values of size n (one per observation), or a list with separate entries if separate\_results is TRUE.

dispersion\_quantile(): a numeric vector with dispersion values (one per observation).

overprediction\_quantile(): a numeric vector with overprediction values (one per observation).

underprediction\_quantile(): a numeric vector with underprediction values (one per observation)

#### **Input format**
